

#8. Positive integrals; the Γ -function

Ex: For $R \geq 1$ and $h > 0$ (and $n \geq 2$) bound

$$\underline{S} = \sum_{k \in \mathbb{Z}^n \setminus \{0\}} (1+|Rk|)^{-\frac{n+1}{2}} (1+|hk|)^{-\frac{n+1}{2}} \quad \underline{\text{optimally!}}$$

Solution, using dyadic decomposition

Using $1+|x| \approx \begin{cases} 1 & \text{if } |x| \ll 1 \\ |x| & \text{if } |x| \gg 1 \end{cases}$ we have

$$\underline{S} \approx R^{-\frac{n+1}{2}} \sum_{k \neq 0} |k|^{-\frac{n+1}{2}} (1+|hk|)^{-\frac{n+1}{2}}$$

$$\approx R^{-\frac{n+1}{2}} \sum_{0 < |k| \leq h^{-1}} |k|^{-\frac{n+1}{2}} + (Rh)^{-\frac{n+1}{2}} \sum_{|k| > h^{-1}} |k|^{-(n+1)}$$

Hence if $h > 1$: $\underline{S} \approx 0 + (Rh)^{-\frac{n+1}{2}}$

Now assume $0 < h \leq 1$

Decompose $\{k \in \mathbb{Z}^n: 0 < |k| \leq h^{-1}\} \subset A_0 \cup A_1 \cup \dots \cup A_M$

where $A_m := \{k \in \mathbb{Z}^n: 2^m \leq |k| < 2^{m+1}\}$

and M minimal with $2^{M+1} > h^{-1}$ ($M \in \mathbb{Z}_{\geq 0}$)

Note $\forall k \in A_m: |k|^{-\frac{n+1}{2}} \leq (2^m)^{-\frac{n+1}{2}}$

Also $\#A_m \leq \#\{k \in \mathbb{Z}^n: |k| < 2^{m+1}\} \ll (2^{m+1})^n \ll 2^{mn}$

Hence $\sum_{0 < |k| \leq h^{-1}} |k|^{-\frac{n+1}{2}} \leq \sum_{m=0}^M \#A_m \cdot (2^m)^{-\frac{n+1}{2}} \ll \sum_{m=0}^M 2^{mn - \frac{m(n+1)}{2}} = \sum_{m=0}^M 2^{\frac{n-1}{2}m}$

using $n \geq 2$ $\lesssim 2^{\frac{n-1}{2}M} \leq \underline{\underline{h^{-\frac{n-1}{2}}}}$
since $2^M \leq h^{-1}$

Similarly, for $\sum_{|k| > h^{-1}} |k|^{-(n+1)}$ (still assuming $0 < h \leq 1$)

Decompose $\{k \in \mathbb{Z}^n : |k| > h^{-1}\} = A_0 \cup A_1 \cup A_2 \cup \dots$

where $A_m = \{k \in \mathbb{Z}^n : h^{-1} 2^m < |k| \leq h^{-1} 2^{m+1}\}$,

$$\begin{aligned} \text{get: } \sum_{|k| > h^{-1}} |k|^{-(n+1)} &\leq \sum_{m=0}^{\infty} \#A_m \cdot (h^{-1} 2^m)^{-(n+1)} \ll \sum_{m=0}^{\infty} (h^{-1} 2^m)^n \cdot (h^{-1} 2^m)^{-(n+1)} \\ &= h \sum_{m=0}^{\infty} 2^{-m} \ll h \end{aligned}$$

$$\text{Hence get } \underline{S} \sim R^{-\frac{n+1}{2}} \sum_{0 < |k| \leq h^{-1}} |k|^{-\frac{n+1}{2}} + (Rh)^{-\frac{n+1}{2}} \sum_{|k| > h^{-1}} |k|^{-(n+1)} \ll \underline{R^{-\frac{n+1}{2}} h^{-\frac{n-1}{2}}}$$

(assuming $0 < h \leq 1$).

Alternative (simpler!)

$$\sum_{\substack{0 < |k| \leq h^{-1}}} |k|^{-\frac{n+1}{2}} \approx \int_{B_{h^{-1}}^n \setminus B_1^n} |x|^{-\frac{n+1}{2}} dx \approx \int_1^{h^{-1}} r^{-\frac{n+1}{2}} \cdot r^{n-1} dr \approx \underline{\underline{h^{-\frac{n-1}{2}}}}$$

Using $|x| \approx |k|$
for all $x \in [-\frac{1}{2}, \frac{1}{2}]^n + k$

polar coordinates

and similarly

$$\sum_{\substack{|k| > h^{-1}}} |k|^{-(n+1)} \approx \int_{\mathbb{R}^n \setminus B_{h^{-1}}^n} |x|^{-(n+1)} dx \approx \int_{h^{-1}}^{\infty} r^{-(n+1)} \cdot r^{n-1} dr \approx \underline{\underline{h}}$$

Ex: How bound $f(x) = \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-x^2t^2)}}$ as $x \rightarrow 1^-$?

(A "complete elliptic integral")

Assume $\frac{1}{2} \leq x < 1$.

Note

$$\int_0^{1/2} \frac{dt}{\sqrt{(1-t^2)(1-x^2t^2)}} \approx 1.$$

Hence the crux

is to understand the integrand for t near 1.

Note $\underline{(1-t^2)(1-x^2t^2)} = (1-t)(1+t)(1-xt)(1+xt) \approx \underline{(1-t)(1-xt)}$

Substitute $t = 1-h$.

$$\therefore \underline{f(x) \approx 1 + \int_0^{1/2} \frac{dh}{\sqrt{h(1-x+hx)}}$$

$$\boxed{\text{For } a, b > 0: \underline{\underline{a+b \asymp \max(a, b)}}$$

Hence $\underline{\underline{1-x+ xh}} \asymp \max(1-x, xh) = \begin{cases} 1-x & \text{if } h \leq \frac{1-x}{x} \\ xh & \text{if } h \geq \frac{1-x}{x} \end{cases} \asymp \underline{\underline{\begin{cases} 1-x & \text{if } h \leq 1-x \\ h & \text{if } h \geq 1-x \end{cases}}}$

Thus $\underline{\underline{f(x)}} \asymp 1 + \int_0^{1-x} \frac{dh}{\sqrt{h(1-x)}} + \int_{1-x}^{1/2} \frac{dh}{\sqrt{h \cdot h}}$

$$= 1 + \underbrace{2\sqrt{\frac{1-x}{1-x}}}_{=1} + \log\left(\frac{1}{2(1-x)}\right)$$

$$= \left(3 + \log\left(\frac{1}{2}\right)\right) + \log\left(\frac{1}{1-x}\right) \asymp \underline{\underline{\log\left(\frac{1}{1-x}\right)}} \quad \underline{\underline{\text{as } x \rightarrow 1^-}}$$

Answer: $\underline{\underline{f(x) = \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-x^2t^2)}} \asymp \log\left(\frac{1}{1-x}\right) \text{ as } x \rightarrow 1^-}}$

The gamma function (see Lecture notes, Sec. 7)

DEF: $\Gamma(s) := \int_0^{\infty} e^{-x} x^{s-1} dx$ for $s \in \mathbb{C}$ with $\operatorname{Re}(s) > 0$.

Using $\Gamma(s+1) \equiv s\Gamma(s)$ one extends the definition of $\Gamma(s)$ to a meromorphic function in all \mathbb{C} , with poles (all simple) at $s = 0, -1, -2, -3, \dots$

Check that $\Gamma(s+1) = s\Gamma(s)$ holds when $\operatorname{Re}(s) > 0$:

$$\begin{aligned} \underline{\Gamma(s+1)} &= \int_0^{\infty} e^{-x} x^s dx = \left[-e^{-x} x^s \right]_0^{\infty} - \int_0^{\infty} (-e^{-x}) \cdot s x^{s-1} dx = 0 + s \int_0^{\infty} e^{-x} x^{s-1} dx \\ &= \underline{s\Gamma(s)}. \end{aligned}$$

Clearly $\Gamma(1) = 1$. Hence $\Gamma(2) = 1$; $\Gamma(3) = 2 \cdot 1$; $\Gamma(4) = 3 \cdot 2 \cdot 1$, etc:

$$\boxed{\begin{aligned} \Gamma(n) &= (n-1)! \\ \forall n \in \mathbb{Z}^+ \end{aligned}}$$

$$\underline{\underline{\Gamma\left(\frac{1}{2}\right) = \int_0^{\infty} e^{-x} x^{-\frac{1}{2}} dx = \{x=u^2\} = 2 \int_0^{\infty} e^{-u^2} du = \underline{\underline{\sqrt{\pi}}}}$$

Hence $\Gamma\left(\frac{3}{2}\right) = \frac{1}{2}\sqrt{\pi}$, $\Gamma\left(\frac{5}{2}\right) = \frac{1}{2} \cdot \frac{3}{2}\sqrt{\pi}$, etc:

$$\Gamma\left(k + \frac{1}{2}\right) = \frac{(2k-1)!!}{2^k} \sqrt{\pi}$$

$$\forall k \in \mathbb{Z}_{\geq 0}$$

Volume of B_1^n : $\underline{\underline{\frac{\pi^{n/2}}{\Gamma\left(\frac{n}{2} + 1\right)}}}$

$$\underline{\underline{\Gamma(s) \Gamma(1-s) \equiv \frac{\pi}{\sin(\pi s)}}}$$

$$\underline{\underline{\Gamma(2s) \equiv \pi^{-\frac{1}{2}} \cdot 2^{2s-1} \Gamma(s) \Gamma\left(s + \frac{1}{2}\right)}}$$

$$\underline{\underline{\frac{1}{\Gamma(s)} \equiv s \cdot e^{\gamma s} \cdot \prod_{n=1}^{\infty} \left(1 + \frac{s}{n}\right) e^{-s/n}}}}$$

with $\underline{\underline{\gamma = \lim_{N \rightarrow \infty} \left(\sum_{n=1}^N \frac{1}{n} - \log N \right) = 0,57722\dots}}$

(Euler's constant)

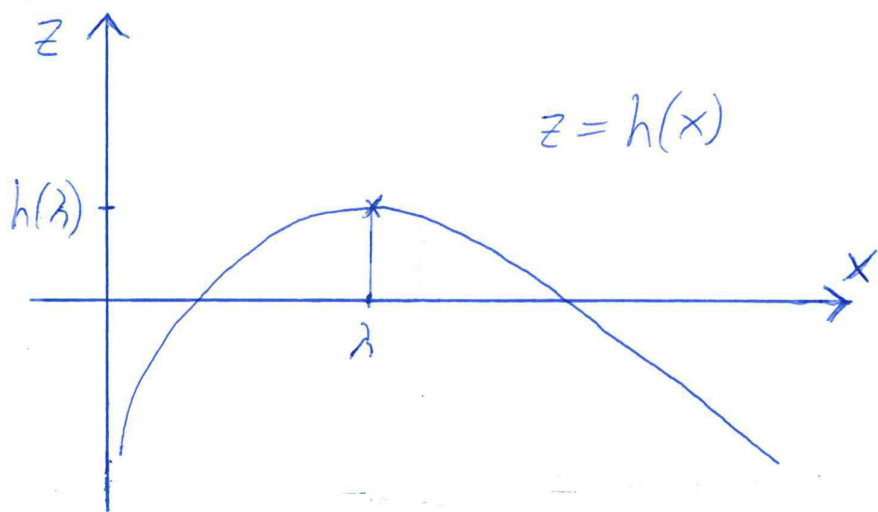

Asymptotic formula for $\Gamma(s) = \int_0^{\infty} e^{-x} x^{s-1} dx$ as $s \rightarrow +\infty$ ($s \in \mathbb{R}$) ?

A positive integral! Cleaner: Set $\lambda := s-1$, study $\Gamma(\lambda+1) = \int_0^{\infty} e^{-x} x^{\lambda} dx$

Study the integrand: $e^{-x} x^{\lambda} = \exp(\underbrace{-x + \lambda \log x}_{= h(x)})$

$$h(x) = -x + \lambda \log x$$

$$h'(x) = -1 + \frac{\lambda}{x}$$

→ Subst. $x = \lambda + y$ ($y > -\lambda$)

$$\Rightarrow \underline{h(\lambda + y)} = \underline{-\lambda - y + \lambda \log(\lambda + y)}$$

$$= \underline{-\lambda \left(1 + \frac{y}{\lambda} - \log(\lambda) - \log\left(1 + \frac{y}{\lambda}\right)\right)}$$

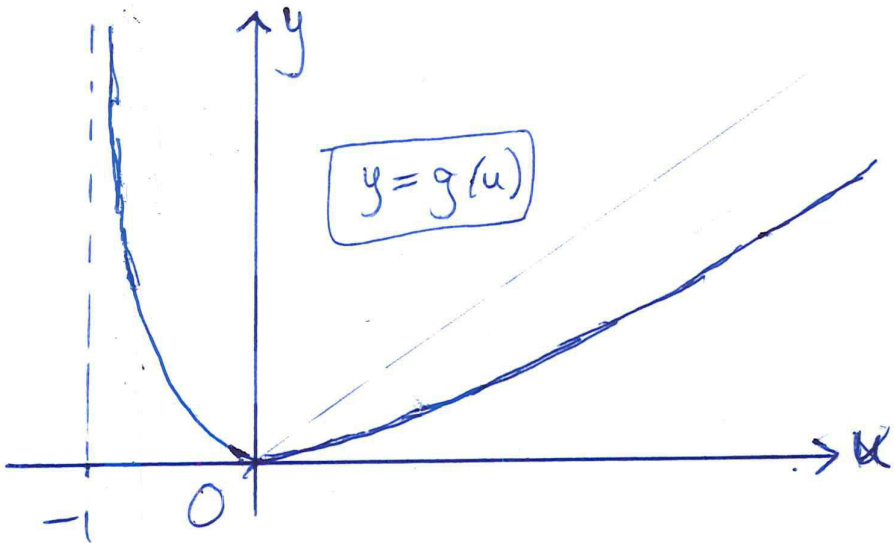

→ subst $y = \lambda u$ ($u > -1$)

$$\Rightarrow \underline{h(\lambda + \lambda u)} = \underline{-\lambda(1 - \log(\lambda)) - \lambda(u - \log(1 + u))}$$

$$\underbrace{\hspace{10em}}_{g(u)}$$

Get (for $\lambda > 0$): $\Gamma(\lambda+1) = \lambda^{\lambda+1} e^{-\lambda} \int_{-1}^{\infty} e^{-\lambda \cdot g(u)} du,$

where $g(u) = u - \log(1+u)$

For u near 0 : $g(u) = \frac{1}{2}u^2 + O(u^3)$

Thus

$e^{-\lambda \cdot g(u)} = \exp\left(-\frac{\lambda}{2}u^2 + O(\lambda|u|^3)\right)$

must require $\lambda|u|^3 \ll 1$

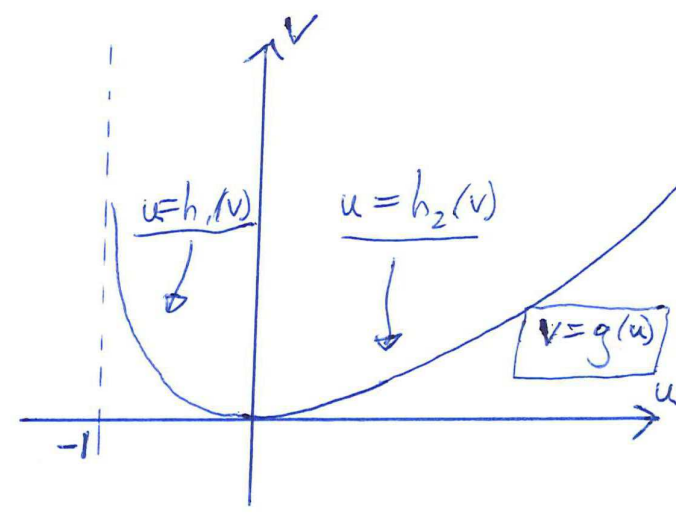

$= e^{-\frac{\lambda}{2}u^2} \cdot (1 + O(\lambda|u|^3))$

$\Gamma(\lambda+1) = \sqrt{2\pi} \lambda^{\lambda+\frac{1}{2}} e^{-\lambda} (1 + O(\lambda^{-\frac{1}{2}}))$ as $\lambda \rightarrow +\infty$

More convenient method (Laplace):

$$\int_{-1}^{\infty} e^{-\lambda \cdot g(u)} du \approx ?$$

Take $v = g(u)$ as new variable of integration!

$$= \int_0^{\infty} e^{-\lambda v} \cdot (-h_1'(v)) dv + \int_0^{\infty} e^{-\lambda v} h_2'(v) dv$$

We have $-h_1'(v) = \frac{1}{\sqrt{2v}} - \frac{2}{3} + \frac{1}{6\sqrt{2}} v^{\frac{1}{2}} + \dots$

Hence, if $c > 0$ is sufficiently small:

$$\int_0^{\infty} e^{-\lambda v} (-h_1'(v)) dv = \int_0^c e^{-\lambda v} \left(\frac{1}{\sqrt{2v}} - \frac{2}{3} + \frac{1}{6\sqrt{2}} \sqrt{v} + O(v) \right) dv + \int_c^{\infty} e^{-\lambda v} (-h_1'(v)) dv$$

Remains to understand: $\int_0^c e^{-\lambda v} \cdot v^{\alpha} dv$ as $\lambda \rightarrow +\infty$,
for $\alpha = -\frac{1}{2}, 0, \frac{1}{2}, \dots$

$\ll \int_c^{\infty} e^{-\lambda v} dv \ll e^{-c\lambda}$
since $|h_1'(v)| = O(v)$
for $v \geq c$

Estimating $\int_0^{\infty} e^{-\lambda v} \cdot v^{\alpha} dv$ as $\lambda \rightarrow +\infty$ (α fixed, $\alpha > -1$)

Note $\int_0^{\infty} e^{-\lambda v} v^{\alpha} dv = \lambda^{-\alpha-1} \cdot \int_0^{c\lambda} e^{-x} x^{\alpha} dx$

= " $\gamma(\alpha+1, c\lambda)$ ", an incomplete gamma function

(See lecture notes, Sec. 7.3)

Surely $\int_0^{c\lambda} e^{-x} x^{\alpha} dx \approx \int_0^{\infty} e^{-x} x^{\alpha} dx = \Gamma(\alpha+1)$, as $\lambda \rightarrow +\infty$ with α fixed.

↑
exponentially close!?

Error: $\int_{c\lambda}^{\infty} e^{-x} x^{\alpha} dx$

If $\alpha \leq 0$: $\int_{c\lambda}^{\infty} e^{-x} x^{\alpha} dx \leq (c\lambda)^{\alpha} \int_{c\lambda}^{\infty} e^{-x} dx = (c\lambda)^{\alpha} e^{-c\lambda}$

If $\alpha > 0$: Integrate by parts!

$$\int_{c\lambda}^{\infty} e^{-x} x^{\alpha} dx = \left[-e^{-x} x^{\alpha} \right]_{c\lambda}^{\infty} + \alpha \int_{c\lambda}^{\infty} e^{-x} x^{\alpha-1} dx = \underline{\underline{e^{-c\lambda} (c\lambda)^{\alpha} + \alpha \int_{c\lambda}^{\infty} e^{-x} x^{\alpha-1} dx}}$$

If $\alpha > 1$: Repeat!

↳ Conclude: For any fixed $\alpha > -1$: $\int_{c\lambda}^{\infty} e^{-x} x^{\alpha} dx \ll \lambda^{\alpha} e^{-c\lambda}$ as $\lambda \rightarrow \infty$.

Hence: $\int_0^{c\lambda} e^{-x} x^{\alpha} dx = \Gamma(\alpha+1) + O(\lambda^{\alpha} e^{-c\lambda})$ as $\lambda \rightarrow \infty$

Hence: $\Gamma(\lambda+1) = \sqrt{2\pi} \lambda^{\lambda+\frac{1}{2}} e^{-\lambda} \cdot \left(1 + \frac{1}{12} \lambda^{-1} + O(\lambda^{-2})\right)$ as $\lambda \rightarrow +\infty$.
