# QUANTITATIVE BOUNDS IN THE CENTRAL LIMIT THEOREM FOR $m$-DEPENDENT RANDOM VARIABLES 

SVANTE JANSON, LUCA PRATELLI, AND PIETRO RIGO

$$
\begin{aligned}
& \text { AbStract. For each } n \geq 1 \text {, let } X_{n, 1}, \ldots, X_{n, N_{n}} \text { be real random variables and } \\
& S_{n}=\sum_{i=1}^{N_{n}} X_{n, i} \text {. Let } m_{n} \geq 1 \text { be an integer. Suppose }\left(X_{n, 1}, \ldots, X_{n, N_{n}}\right) \text { is } \\
& m_{n} \text {-dependent, } E\left(X_{n i}\right)=0, E\left(X_{n i}^{2}\right)<\infty \text { and } \sigma_{n}^{2}:=E\left(S_{n}^{2}\right)>0 \text { for all } n \text { and } \\
& \text { i. Then, } \\
& \qquad d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 30\left\{c^{1 / 3}+12 U_{n}(c / 2)^{1 / 2}\right\} \quad \text { for all } n \geq 1 \text { and } c>0 \text {, } \\
& \text { where } d_{W} \text { is Wasserstein distance, } Z \text { a standard normal random variable and } \\
& \qquad U_{n}(c)=\frac{m_{n}}{\sigma_{n}^{2}} \sum_{i=1}^{N_{n}} E\left[X_{n, i}^{2} 1\left\{\left|X_{n, i}\right|>c \sigma_{n} / m_{n}\right\}\right] .
\end{aligned}
$$

Among other things, this estimate of $d_{W}\left(S_{n} / \sigma_{n}, Z\right)$ yields a similar estimate of $d_{T V}\left(S_{n} / \sigma_{n}, Z\right)$ where $d_{T V}$ is total variation distance.

## 1. Introduction

Central limit theorems (CLTs) for $m$-dependent random variables have a long history. Pioneering results, for a fixed $m$, were given by Hoeffding and Robbins [15] and Diananda [11] (for $m$-dependent sequences), and Orey [17] (more generally, and also for triangular arrays). These results were then extended to the case of increasing $m=m_{n}$; see e.g. Bergström [1], Berk [2], Rio [20], Romano and Wolf [22], and Utev [24], [25].

Obviously, CLTs for $m$-dependent random variables are often corollaries of more general results obtained under mixing conditions. A number of CLTs under mixing conditions are actually available. Without any claim of being exhaustive, we mention [3], [10], [18], [20], [24], [25] and references therein. However, mixing conditions are not directly related to our purposes (as stated below) and they will not be discussed further.

This paper deals with an $\left(m_{n}\right)$-dependent array of random variables, where $\left(m_{n}\right)$ is any sequence of integers, and provides an upper bound for the Wasserstein distance between the standard normal law and the distribution of the normalized partial sums. A related bound for the total variation distance is obtained as well. To be more precise, we need some notation.

[^0]For each $n \geq 1$, let $1 \leq m_{n} \leq N_{n}$ be integers, $\left(X_{n, 1}, \ldots, X_{n, N_{n}}\right)$ a collection of real random variables, and

$$
S_{n}=\sum_{i=1}^{N_{n}} X_{n, i}
$$

Suppose

$$
\begin{equation*}
\left(X_{n, 1}, \ldots, X_{n, N_{n}}\right) \text { is } m_{n} \text {-dependent for every } n \tag{1}
\end{equation*}
$$

$$
\begin{equation*}
E\left(X_{n i}\right)=0, \quad E\left(X_{n i}^{2}\right)<\infty, \quad \sigma_{n}^{2}:=E\left(S_{n}^{2}\right)>0 \quad \text { for all } n \text { and } i, \tag{2}
\end{equation*}
$$

and define

$$
U_{n}(c)=\frac{m_{n}}{\sigma_{n}^{2}} \sum_{i=1}^{N_{n}} E\left[X_{n, i}^{2} 1\left\{\left|X_{n, i}\right|>c \sigma_{n} / m_{n}\right\}\right] \quad \text { for all } c>0
$$

Our main result (Theorem 4) is that
(3) $\quad d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 30\left\{c^{1 / 3}+12 U_{n}(c / 2)^{1 / 2}\right\} \quad$ for all $n \geq 1$ and $c>0$,
where $d_{W}$ is Wasserstein distance and $Z$ a standard normal random variable.
Inequality (3) provides a quantitative estimate of $d_{W}\left(S_{n} / \sigma_{n}, Z\right)$. The connections between (3) and other analogous results are discussed in Remark 12 and Section 4. To our knowledge, however, no similar estimate of $d_{W}\left(S_{n} / \sigma_{n}, Z\right)$ is available under conditions (1)-(2) only. In addition, inequality (3) implies the following useful result:

Theorem 1 (Utev [24, 25]). $S_{n} / \sigma_{n} \xrightarrow{\text { dist }} Z$ provided conditions (1)-(2) hold and $U_{n}(c) \rightarrow 0$ for every $c>0$.

Based on inequality (3), we also obtain quantitative bounds for $d_{K}\left(S_{n} / \sigma_{n}, Z\right)$ and $d_{T V}\left(S_{n} / \sigma_{n}, Z\right)$, where $d_{K}$ and $d_{T V}$ are Kolmogorov distance and total variation distance, respectively. As to $d_{K}$, it suffices to recall that

$$
d_{K}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 2 \sqrt{d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right)}
$$

see Lemma 2. To estimate $d_{T V}$, define

$$
l_{n}=2 \int_{0}^{\infty} t\left|\phi_{n}(t)\right| d t
$$

where $\phi_{n}$ is the characteristic function of $S_{n} / \sigma_{n}$. By a result in [19] (see Theorem 3 below),

$$
d_{T V}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 2 d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right)^{1 / 2}+l_{n}^{2 / 3} d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right)^{1 / 3}
$$

Hence, $d_{T V}\left(S_{n} / \sigma_{n}, Z\right)$ can be upper bounded via inequality (3). For instance, in addition to (1)-(2), suppose $X_{n i} \in L_{\infty}$ for all $n$ and $i$ and define

$$
c_{n}=\frac{2 m_{n}}{\sigma_{n}} \max _{i}\left\|X_{n i}\right\|_{\infty}
$$

On noting that $U_{n}\left(c_{n} / 2\right)=0$, one obtains

$$
d_{T V}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq \sqrt{120} c_{n}^{1 / 6}+30^{1 / 3} l_{n}^{2 / 3} c_{n}^{1 / 9}
$$

The rest of this paper is organized as follows. Section 2 just recalls some definitions and known results, Section 3 is devoted to proving inequality (3), while Section 4 investigates $d_{T V}\left(S_{n} / \sigma_{n}, Z\right)$ and the convergence rate provided by (3). Section 5 contains some examples that illustrate the main results. Section 6 ends the paper with an extension that does not require ( $m_{n}$ )-dependence (but uses some other conditions).

The numerical constants in our results are obviously not best possible; we have not tried to optimize them. More important are the powers, $c^{1 / 3}$ and $U_{n}(c / 2)^{1 / 2}$ in (3) and similar powers in other results; we do not believe that these are optimal. This is discussed in Section 4. How far (3) can be improved, however, is essentially an open problem.

## 2. Preliminaries

The same notation as in Section 1 is adopted in the sequel. It is implicitly assumed that, for each $n \geq 1$, the variables ( $X_{n i}: 1 \leq i \leq N_{n}$ ) are defined on the same probability space (which may depend on $n$ ).

Let $k \geq 0$ be an integer. A (finite or infinite) sequence $\left(Y_{i}\right)$ of random variables is $k$-dependent if ( $Y_{i}: i \leq j$ ) is independent of ( $Y_{i}: i>j+k$ ) for every $j$. In particular, 0 -dependent is the same as independent. Given a sequence $\left(k_{n}\right)$ of nonnegative integers, an array ( $Y_{n i}: n \geq 1,1 \leq i \leq N_{n}$ ) is said to be $\left(k_{n}\right)$-dependent if $\left(Y_{n i}: 1 \leq i \leq N_{n}\right)$ is $k_{n}$-dependent for every $n$.

Let $X$ and $Y$ be real random variables. Three well known distances between their probability distributions are Wasserstein's, Kologorov's and total variation. Kolmogorov distance and total variation distance are, respectively,

$$
\begin{aligned}
& d_{K}(X, Y)=\sup _{t \in \mathbb{R}}|P(X \leq t)-P(Y \leq t)| \quad \text { and } \\
& d_{T V}(X, Y)=\sup _{A \in \mathcal{B}(\mathbb{R})}|P(X \in A)-P(Y \in A)|
\end{aligned}
$$

Under the assumption $E|X|+E|Y|<\infty$, Wasserstein distance is

$$
d_{W}(X, Y)=\inf _{U \sim X, V \sim Y} E|U-V|
$$

where inf is over the real random variables $U$ and $V$, defined on the same probability space, such that $U \sim X$ and $V \sim Y$. Equivalently,

$$
d_{W}(X, Y)=\int_{-\infty}^{\infty}|P(X \leq t)-P(Y \leq t)| d t=\sup _{f}|E f(X)-E f(Y)|
$$

where sup is over the 1 -Lipschitz functions $f: \mathbb{R} \rightarrow \mathbb{R}$. The next lemma is certainly known, but we give a proof since we do not know of any reference for the first claims.

Lemma 2. Suppose $E X^{2} \leq 1, E Y^{2} \leq 1$ and $E Y=0$. Then,

$$
\begin{aligned}
d_{W}(X, Y) & \leq \sqrt{2} \\
d_{W}(X, Y) & \leq 4 \sqrt{d_{K}(X, Y)}
\end{aligned}
$$

If $Y \sim N(0,1)$, we also have

$$
d_{K}(X, Y) \leq 2 \sqrt{d_{W}(X, Y)}
$$

Proof. Take $U$ independent of $V$ with $U \sim X$ and $V \sim Y$. Then,

$$
d_{W}(X, Y) \leq E|U-V| \leq\left\{E\left((U-V)^{2}\right)\right\}^{1 / 2} \leq \sqrt{2}
$$

Moreover, for each $c>0$,

$$
\begin{aligned}
d_{W}(X, Y) & =\int_{-\infty}^{\infty}|P(X \leq t)-P(Y \leq t)| d t \\
& \leq 2 c d_{K}(X, Y)+\int_{c}^{\infty}|P(X>t)-P(Y>t)| d t \\
& +\int_{c}^{\infty}|P(-X>t)-P(-Y>t)| d t \\
& \leq 2 c d_{K}(X, Y)+\int_{c}^{\infty}\{P(|X|>t)+P(|Y|>t)\} d t \\
& \leq 2 c d_{K}(X, Y)+\int_{c}^{\infty} \frac{2}{t^{2}} d t=2 c d_{K}(X, Y)+\frac{2}{c}
\end{aligned}
$$

Hence, letting $c=d_{K}(X, Y)^{-1 / 2}$, one obtains $d_{W}(X, Y) \leq 4 \sqrt{d_{K}(X, Y)}$.
Finally, if $Y \sim N(0,1)$, it is well known that $d_{K}(X, Y) \leq 2 \sqrt{d_{W}(X, Y)}$; see e.g. [7, Theorem 3.3].

Finally, under some conditions, $d_{T V}$ can be estimated through $d_{W}$. We report a result which allows this; in our setting we simply take $V=1$ below.

Theorem 3 (A version of [19, Theorem 1]). Let $X_{n}, V, Z$ be real random variables, and suppose that $Z \sim N(0,1), V>0, E V^{2}=E X_{n}^{2}=1$ for all $n$, and $V$ is independent of $Z$. Let $\phi_{n}$ be the characteristic function of $X_{n}$, and

$$
l_{n}=2 \int_{0}^{\infty} t\left|\phi_{n}(t)\right| d t
$$

Then,

$$
d_{T V}\left(X_{n}, V Z\right) \leq\{1+E(1 / V)\} d_{W}\left(X_{n}, V Z\right)^{1 / 2}+l_{n}^{2 / 3} d_{W}\left(X_{n}, V Z\right)^{1 / 3}
$$

for each $n$.
Proof. This is essentially a special case of [19, Theorem 1], with $\beta=2$ and the constant $k$ made explicit. Also, the assumption $d_{W}\left(X_{n}, V Z\right) \rightarrow 0$ in [19, Theorem 1] is not needed; we use instead $d_{W}\left(X_{n}, V Z\right) \leq \sqrt{2}$ from Lemma 2. Using this and $E X_{n}^{2}=1$, the various constants appearing in the proof can be explicitly evaluated. In fact, improving the argument in [19] slightly by using $P\left(\left|X_{n}\right|>t\right) \leq E X_{n}^{2} / t^{2}=$ $t^{-2}$, and as just said using $d_{W}\left(X_{n}, V Z\right) \leq \sqrt{2}$, we can take $k^{*}=5+4 \sqrt{2}$ in the proof. After simple calculations, this implies that the constant $k$ in [19] can be taken as

$$
k=\frac{1}{2} \cdot \frac{3}{2} \cdot 2^{1 / 3}(5+4 \sqrt{2})^{1 / 3} \pi^{-2 / 3}<1
$$

## 3. An upper bound for Wasserstein distance

As noted in Section 1, our main result is:
Theorem 4. Under conditions (1)-(2),

$$
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 30\left\{c^{1 / 3}+12 U_{n}(c / 2)^{1 / 2}\right\}
$$

for all $n \geq 1$ and $c>0$, where $Z$ denotes a standard normal random variable.
Before proceeding, we note a simple special case for bounded random variables.
Corollary 5. Suppose that conditions (1)-(2) hold and

$$
\begin{equation*}
\max _{i}\left|X_{n, i}\right| \leq \sigma_{n} \gamma_{n} \quad \text { a.s. for some constants } \gamma_{n} \tag{4}
\end{equation*}
$$

Then,

$$
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 30 \cdot 2^{1 / 3}\left(m_{n} \gamma_{n}\right)^{1 / 3} \leq 40\left(m_{n} \gamma_{n}\right)^{1 / 3}
$$

where $Z$ denotes a standard normal random variable.
Proof. Take $c=2 m_{n} \gamma_{n}$ in Theorem 4 and note that $U_{n}(c / 2)=0$.
In turn, Theorem 4 follows from the following result, which is a sharper version of the special case $m_{n}=1$.

Theorem 6. Let $X_{1}, \ldots, X_{N}$ be real random variables and $S=\sum_{i=1}^{N} X_{i}$. Suppose $\left(X_{1}, \ldots, X_{N}\right)$ is 1-dependent and

$$
E\left(X_{i}\right)=0, E\left(X_{i}^{2}\right)<\infty \text { for all } i \text { and } \sigma^{2}:=E\left(S^{2}\right)>0 .
$$

Then,

$$
d_{W}\left(\frac{S}{\sigma}, Z\right) \leq 30\left\{c^{1 / 3}+6 L(c)^{1 / 2}\right\} \quad \text { for all } c>0
$$

where $Z$ is a standard normal random variable and

$$
L(c)=\frac{1}{\sigma^{2}} \sum_{i=1}^{N} E\left[X_{i}^{2} 1\left\{\left|X_{i}\right|>c \sigma\right\}\right]
$$

To deduce Theorem 4 from Theorem 6, define $M_{n}=\left\lceil N_{n} / m_{n}\right\rceil, X_{n, i}=0$ for $i>N_{n}$, and

$$
Y_{n, i}=\sum_{j=(i-1) m_{n}+1}^{i m_{n}} X_{n, j} \quad \text { for } i=1, \ldots, M_{n}
$$

Since $\left(Y_{n, 1}, \ldots, Y_{n, M_{n}}\right)$ is 1-dependent and $\sum_{i} Y_{n, i}=\sum_{i} X_{n, i}=S_{n}$, Theorem 6 implies

$$
\begin{equation*}
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 30\left\{c^{1 / 3}+6 L_{n}(c)^{1 / 2}\right\} \tag{5}
\end{equation*}
$$

where

$$
L_{n}(c)=\frac{1}{\sigma_{n}^{2}} \sum_{i=1}^{M_{n}} E\left[Y_{n, i}^{2} 1\left\{\left|Y_{n, i}\right|>c \sigma_{n}\right\}\right]
$$

Therefore, to obtain Theorem 4, it suffices to note the following inequality:

Lemma 7. With notations as above, for every $c>0$,

$$
L_{n}(2 c) \leq 4 U_{n}(c)
$$

In the rest of this section, we prove Lemma 7 and Theorem 6 . We also obtain a (very small) improvement of Utev's Theorem 1.

### 3.1. Proof of Lemma 7 and Utev's theorem.

Proof of Lemma 7. Fix $c>0$ and define

$$
V_{n, i}=\sum_{j=(i-1) m_{n}+1}^{i m_{n}} X_{n, j} 1\left\{\left|X_{n, j}\right|>c \sigma_{n} / m_{n}\right\}
$$

Since $\left|Y_{n, i}\right| \leq\left|V_{n, i}\right|+c \sigma_{n}$, one obtains

$$
\left|Y_{n, i}\right| 1\left\{\left|Y_{n, i}\right|>2 c \sigma_{n}\right\} \leq\left(\left|V_{n, i}\right|+c \sigma_{n}\right) 1\left\{\left|V_{n, i}\right|>c \sigma_{n}\right\} \leq 2\left|V_{n, i}\right| .
$$

Therefore,

$$
\begin{aligned}
\sigma_{n}^{2} L_{n}(2 c) & =\sum_{i=1}^{M_{n}} E\left[Y_{n, i}^{2} 1\left\{\left|Y_{n, i}\right|>2 c \sigma_{n}\right\}\right] \leq 4 \sum_{i=1}^{M_{n}} E\left(V_{n, i}^{2}\right) \\
& \leq 4 m_{n} \sum_{i=1}^{M_{n}} \sum_{j=(i-1) m_{n}+1}^{i m_{n}} E\left[X_{n, j}^{2} 1\left\{\left|X_{n, j}\right|>c \sigma_{n} / m_{n}\right\}\right] \\
& =4 m_{n} \sum_{i=1}^{N_{n}} E\left[X_{n, i}^{2} 1\left\{\left|X_{n, i}\right|>c \sigma_{n} / m_{n}\right\}\right]=4 \sigma_{n}^{2} U_{n}(c) .
\end{aligned}
$$

We also note that, because of (5), Theorem 6 implies:
Corollary 8. $S_{n} / \sigma_{n} \xrightarrow{\text { dist }} Z$ if conditions $(1)-(2)$ hold and $L_{n}(c) \rightarrow 0$ for every $c>0$.

Corollary 8 slightly improves Theorem 1 . In fact, $U_{n}(c) \rightarrow 0$ for all $c>0$ implies $L_{n}(c) \rightarrow 0$ for all $c>0$, because of Lemma 7 , but the converse is not true.
Example 9. $\left(L_{n}(c) \rightarrow 0\right.$ does not imply $\left.U_{n}(c) \rightarrow 0\right)$. Let $\left(V_{n}: n \geq 1\right)$ be an i.i.d. sequence of real random variables such that $V_{1}$ is absolutely continuous with density $f(x)=(3 / 2) x^{-4} 1_{[1, \infty)}(|x|)$. Let $m_{n}$ and $t_{n}$ be positive integers such that $m_{n} \rightarrow \infty$. Define $N_{n}=m_{n}\left(t_{n}+1\right)$ and

$$
X_{n, i}=V_{i} \text { if } 1 \leq i \leq m_{n} t_{n} \quad \text { and } \quad X_{n, i}=V_{m_{n} t_{n}+1} \quad \text { if } m_{n} t_{n}<i \leq m_{n}\left(t_{n}+1\right) .
$$

Define also

$$
T_{n}=\frac{\sum_{j=1}^{m_{n}} V_{j}}{\sqrt{m_{n}}}
$$

Then, $E V_{1}^{2}=3, \sigma_{n}^{2}=3\left(m_{n} t_{n}+m_{n}^{2}\right)$ and

$$
\begin{aligned}
L_{n}(c) & =\frac{1}{\sigma_{n}^{2}} \sum_{i=1}^{M_{n}} E\left[Y_{n, i}^{2} 1\left\{\left|Y_{n, i}\right|>c \sigma_{n}\right\}\right] \leq \frac{1}{\sigma_{n}^{2}} \sum_{i=1}^{t_{n}} E\left[Y_{n, i}^{2} 1\left\{\left|Y_{n, i}\right|>c \sigma_{n}\right\}\right]+\frac{3 m_{n}^{2}}{\sigma_{n}^{2}} \\
& =\frac{m_{n} t_{n}}{\sigma_{n}^{2}} E\left[T_{n}^{2} 1\left\{\left|T_{n}\right|>c \sigma_{n} / \sqrt{m_{n}}\right\}\right]+\frac{3 m_{n}^{2}}{\sigma_{n}^{2}}
\end{aligned}
$$

If $m_{n}=\mathrm{o}\left(t_{n}\right)$, then $m_{n}^{2} / \sigma_{n}^{2} \rightarrow 0, m_{n} t_{n} / \sigma_{n}^{2} \rightarrow 1 / 3$ and $\sigma_{n} / \sqrt{m_{n}} \rightarrow \infty$. Moreover, the sequence $\left(T_{n}^{2}\right)$ is uniformly integrable (since $T_{n} \xrightarrow{\text { dist }} N(0,3)$ with (trivial) convergence of second moments). Hence, if $m_{n}=\mathrm{o}\left(t_{n}\right)$, one obtains, for every $c>0$,

$$
\underset{n}{\limsup } L_{n}(c) \leq \frac{1}{3} \limsup _{n} E\left[T_{n}^{2} 1\left\{\left|T_{n}\right|>c \sigma_{n} / \sqrt{m_{n}}\right\}\right]=0
$$

However,

$$
\begin{aligned}
U_{n}(c) & =\frac{m_{n}}{\sigma_{n}^{2}} \sum_{i=1}^{N_{n}} E\left[X_{n, i}^{2} 1\left\{\left|X_{n, i}\right|>c \sigma_{n} / m_{n}\right\}\right]=\frac{m_{n} N_{n}}{\sigma_{n}^{2}} E\left[V_{1}^{2} 1\left\{\left|V_{1}\right|>c \sigma_{n} / m_{n}\right\}\right] \\
& =\frac{3 m_{n} N_{n}}{\sigma_{n}^{2}} \int_{c \sigma_{n} / m_{n}}^{\infty} x^{-2} d x=\frac{3 N_{n}}{c \sigma_{n}^{2}} \frac{m_{n}^{2}}{\sigma_{n}} \geq \frac{3 t_{n} m_{n}^{3}}{c\left(6 m_{n} t_{n}\right)^{3 / 2}}
\end{aligned}
$$

for each $n$ such that $c \sigma_{n} / m_{n} \geq 1$ and $m_{n} \leq t_{n}$. Therefore, $L_{n}(c) \rightarrow 0$ and $U_{n}(c) \rightarrow \infty$ for all $c>0$ whenever $m_{n}=\mathrm{o}\left(t_{n}\right)$ and $t_{n}=\mathrm{o}\left(m_{n}^{3}\right)$. This happens, for instance, if $m_{n} \rightarrow \infty$ and $t_{n}=m_{n}^{2}$.
3.2. Proof of Theorem 6. Our proof of Theorem 6 requires three lemmas. A result by Röllin [21] plays a crucial role in one of them (Lemma 11).

In this subsection, $X_{1}, \ldots, X_{N}$ are real random variables and $S=\sum_{i=1}^{N} X_{i}$. We assume that $\left(X_{1}, \ldots, X_{N}\right)$ is 1-dependent and

$$
E\left(X_{i}\right)=0, E\left(X_{i}^{2}\right)<\infty \text { for all } i \text { and } \sigma^{2}:=E\left(S^{2}\right)>0
$$

Moreover, $Z$ is a standard normal random variable independent of $\left(X_{1}, \ldots, X_{N}\right)$.
For each $i=1, \ldots, N$, define

$$
Y_{i}=X_{i}-E\left(X_{i} \mid \mathcal{F}_{i-1}\right)+E\left(X_{i+1} \mid \mathcal{F}_{i}\right)
$$

where $\mathcal{F}_{0}$ is the trivial $\sigma$-field, $\mathcal{F}_{i}=\sigma\left(X_{1}, \ldots, X_{i}\right)$ and $X_{N+1}=0$. Then,

$$
E\left(Y_{i} \mid \mathcal{F}_{i-1}\right)=0 \text { for all } i \text { and } \sum_{i=1}^{N} Y_{i}=\sum_{i=1}^{N} X_{i}=S \text { a.s. }
$$

Lemma 10. Let $\gamma>0$ be a constant and $V^{2}=\sum_{i=1}^{N} E\left(Y_{i}^{2} \mid \mathcal{F}_{i-1}\right)$. Then,

$$
E\left\{\left(\frac{V^{2}}{\sigma^{2}}-1\right)^{2}\right\} \leq 16 \gamma^{2}
$$

provided $\max _{i}\left|X_{i}\right| \leq \sigma \gamma / 3$ a.s.
Proof. First note that

$$
\sigma^{2}=E\left(S^{2}\right)=E\left\{\left(\sum_{i=1}^{N} Y_{i}\right)^{2}\right\}=\sum_{i=1}^{N} E\left(Y_{i}^{2}\right)=E\left(\sum_{i=1}^{N} Y_{i}^{2}\right)
$$

Moreover, since $\max _{i}\left|Y_{i}\right| \leq \gamma \sigma$ a.s., one obtains

$$
\sum_{i=1}^{N} E\left(Y_{i}^{4}\right) \leq \gamma^{2} \sigma^{2} \sum_{i=1}^{N} E\left(Y_{i}^{2}\right)=\gamma^{2} \sigma^{4}
$$

Therefore,

$$
\begin{aligned}
& E\left\{\left(\frac{V^{2}}{\sigma^{2}}-1\right)^{2}\right\} \leq \frac{2}{\sigma^{4}}\left\{E\left[\left(\sum_{i=1}^{N}\left(E\left(Y_{i}^{2} \mid \mathcal{F}_{i-1}\right)-Y_{i}^{2}\right)\right)^{2}\right]+\operatorname{Var}\left(\sum_{i=1}^{N} Y_{i}^{2}\right)\right\} \\
&= \frac{2}{\sigma^{4}}\left\{\sum_{i=1}^{N} E\left(Y_{i}^{4}-E\left(Y_{i}^{2} \mid \mathcal{F}_{i-1}\right)^{2}\right)+\sum_{i=1}^{N} \operatorname{Var}\left(Y_{i}^{2}\right)\right. \\
&\left.+2 \sum_{1 \leq i<j \leq N} \operatorname{Cov}\left(Y_{i}^{2}, Y_{j}^{2}\right)\right\} \\
& \leq \frac{4}{\sigma^{4}}\left\{\sum_{i=1}^{N} E\left(Y_{i}^{4}\right)+\sum_{1 \leq i<j \leq N} \operatorname{Cov}\left(Y_{i}^{2}, Y_{j}^{2}\right)\right\} \\
& \leq 4 \gamma^{2}+\frac{4}{\sigma^{4}} \sum_{1 \leq i<j \leq N} \operatorname{Cov}\left(Y_{i}^{2}, Y_{j}^{2}\right) .
\end{aligned}
$$

To estimate the covariance part, define

$$
Q_{i}=Y_{i}^{2}-E\left(Y_{i}^{2}\right) \quad \text { and } \quad T_{i}=\sum_{k=1}^{i} Y_{k}=\sum_{k=1}^{i} X_{k}+E\left(X_{i+1} \mid \mathcal{F}_{i}\right)
$$

For each fixed $1 \leq i<N$, since $\left(T_{1}, \ldots, T_{N}\right)$ is a martingale,

$$
\begin{aligned}
\sum_{j>i} \operatorname{Cov}\left(Y_{i}^{2}, Y_{j}^{2}\right) & =\sum_{j>i} E\left(Q_{i} Y_{j}^{2}\right)=E\left\{Q_{i} \sum_{j>i} Y_{j}^{2}\right\}=E\left\{Q_{i}\left(T_{N}-T_{i}\right)^{2}\right\} \\
& =E\left\{Q_{i}\left(T_{N}-T_{i+1}\right)^{2}\right\}+E\left(Q_{i} Y_{i+1}^{2}\right) \\
& \leq E\left\{Q_{i}\left(T_{N}-T_{i+1}\right)^{2}\right\}+E\left(Y_{i}^{4}\right)+E\left(Y_{i+1}^{4}\right)
\end{aligned}
$$

Finally, since $\left(X_{1}, \ldots, X_{N}\right)$ is 1-dependent, $E Q_{i}=0$ and $E X_{j}=0$,

$$
\begin{aligned}
E\left\{Q_{i}\left(T_{N}-T_{i+1}\right)^{2}\right\} & =E\left\{Q_{i}\left(\sum_{k=i+2}^{N} X_{k}-E\left(X_{i+2} \mid \mathcal{F}_{i+1}\right)\right)^{2}\right\} \\
& =E\left\{Q_{i}\left(E\left(X_{i+2} \mid \mathcal{F}_{i+1}\right)^{2}-2 X_{i+2} E\left(X_{i+2} \mid \mathcal{F}_{i+1}\right)\right)\right\} \\
& =-E\left\{Q_{i} E\left(X_{i+2} \mid \mathcal{F}_{i+1}\right)^{2}\right\} \\
& \leq E\left(Y_{i}^{2}\right) E\left\{E\left(X_{i+2} \mid \mathcal{F}_{i+1}\right)^{2}\right\} \leq \gamma^{2} \sigma^{2} E\left(Y_{i}^{2}\right)
\end{aligned}
$$

To sum up,

$$
E\left\{\left(\frac{V^{2}}{\sigma^{2}}-1\right)^{2}\right\} \leq 4 \gamma^{2}+\frac{4}{\sigma^{4}} \sum_{i=1}^{N-1}\left(E\left(Y_{i}^{4}\right)+E\left(Y_{i+1}^{4}\right)+\gamma^{2} \sigma^{2} E\left(Y_{i}^{2}\right)\right) \leq 16 \gamma^{2}
$$

Lemma 11. If $\max _{i}\left|X_{i}\right| \leq \sigma \gamma / 3$ a.s., then

$$
d_{W}\left(\frac{S}{\sigma}, Z\right) \leq 15 \gamma^{1 / 3}
$$

Proof. By Lemma $2, d_{W}(S / \sigma, Z) \leq \sqrt{2}$. Hence, it can be assumed that $\gamma \leq 1$.

Define

$$
\begin{gathered}
\tau=\max \left\{m: 1 \leq m \leq N, \sum_{k=1}^{m} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right) \leq 1\right\} \\
J_{i}=1\{\tau \geq i\} \frac{Y_{i}}{\sigma}+1\{\tau=i-1\}\left(1-\sum_{k=1}^{i-1} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)\right)^{1 / 2} Z \quad \text { for } i=1, \ldots, N \\
J_{N+1}=1\{\tau=N\}\left(1-\sum_{k=1}^{N} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)\right)^{1 / 2} Z
\end{gathered}
$$

Since $\tau$ is a stopping time, $Z$ is independent of $\left(X_{1}, \ldots, X_{N}\right)$, and $E\left(Y_{i} \mid \mathcal{F}_{i-1}\right)=0$, one obtains

$$
E\left(J_{i} \mid \mathcal{F}_{i-1}\right)=0 \text { for all } i \text { and } \sum_{k=1}^{N+1} E\left(J_{k}^{2} \mid \mathcal{F}_{k-1}\right)=1 \text { a.s. }
$$

Therefore, for each $a>0$, a result by Röllin [21, Theorem 2.1] implies

$$
d_{W}\left(\sum_{i=1}^{N+1} J_{i}, Z\right) \leq 2 a+\frac{3}{a^{2}} \sum_{i=1}^{N+1} E\left|J_{i}\right|^{3}
$$

To estimate $E\left|J_{i}\right|^{3}$ for $i \leq N$, note that $E|Z|^{3} \leq 2$ and $(1 / \sigma) \max _{i}\left|Y_{i}\right| \leq \gamma$ a.s. Therefore, for $1 \leq i \leq N$,

$$
\begin{aligned}
E\left|J_{i}\right|^{3}= & E\left\{1\{\tau \geq i\} \frac{\left|Y_{i}\right|^{3}}{\sigma^{3}}\right\}+E\left\{1\{\tau=i-1\}\left(1-\sum_{k=1}^{i-1} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)\right)^{3 / 2}|Z|^{3}\right\} \\
\leq & \gamma E\left\{1\{\tau \geq i\} \frac{Y_{i}^{2}}{\sigma^{2}}\right\} \\
& +E\left\{1\{\tau=i-1\}\left(1-\sum_{k=1}^{i-1} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)\right)^{1 / 2}\right\} E|Z|^{3} \\
\leq & \gamma E\left\{1\{\tau \geq i\} \frac{Y_{i}^{2}}{\sigma^{2}}\right\} \\
& +2 E\left\{1\{\tau=i-1\}\left(\sum_{k=1}^{i} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)-\sum_{k=1}^{i-1} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)\right)^{1 / 2}\right\} \\
= & \gamma E\left\{1\{\tau \geq i\} \frac{Y_{i}^{2}}{\sigma^{2}}\right\}+2 E\left\{1\{\tau=i-1\} E\left(Y_{i}^{2} / \sigma^{2} \mid \mathcal{F}_{i-1}\right)^{1 / 2}\right\} \\
\leq & \gamma E\left\{1\{\tau \geq i\} \frac{Y_{i}^{2}}{\sigma^{2}}\right\}+2 \gamma P(\tau=i-1) .
\end{aligned}
$$

Hence,

$$
\sum_{i=1}^{N} E\left|J_{i}\right|^{3} \leq \gamma E\left[\sum_{i=1}^{N} \frac{Y_{i}^{2}}{\sigma^{2}}\right]+2 \gamma=3 \gamma
$$

Similarly,

$$
\begin{aligned}
E\left|J_{N+1}\right|^{3} & =E\left\{1\{\tau=N\}\left(1-\sum_{k=1}^{N} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)\right)^{3 / 2}\right\} E|Z|^{3} \\
& \leq 2 E\left\{1\{\tau=N\}\left(1-\sum_{k=1}^{N} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)\right)\right\} \\
& \leq 2 E\left\{\left(1-\sum_{k=1}^{N} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)\right)^{2}\right\}^{1 / 2} \\
& =2 E\left\{\left(1-\frac{V^{2}}{\sigma^{2}}\right)^{2}\right\}^{1 / 2} \leq 8 \gamma
\end{aligned}
$$

where the last inequality is due to Lemma 10. It follows that

$$
d_{W}\left(\sum_{i=1}^{N+1} J_{i}, Z\right) \leq 2 a+\frac{3}{a^{2}}(3 \gamma+8 \gamma)=2 a+\frac{33 \gamma}{a^{2}}
$$

for each $a>0$. Choosing $a=3 \gamma^{1 / 3}$, this yields

$$
d_{W}\left(\sum_{i=1}^{N+1} J_{i}, Z\right) \leq\left(6+\frac{11}{3}\right) \gamma^{1 / 3} \leq 10 \gamma^{1 / 3}
$$

Next, we estimate $d_{W}\left(S / \sigma, \sum_{i=1}^{N} J_{i}\right)$. To this end, we let

$$
W_{i}=\sum_{k=1}^{i} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)
$$

and we note that

$$
\begin{aligned}
\frac{S}{\sigma}-\sum_{i=1}^{N} J_{i} & =\sum_{i=1}^{N}\left(\frac{Y_{i}}{\sigma}-J_{i}\right)=\sum_{i=1}^{N} 1\{\tau<i\}\left(\frac{Y_{i}}{\sigma}-J_{i}\right) \\
& =\sum_{i=1}^{N-1} 1\{\tau=i\}\left\{\sum_{k=i+1}^{N} \frac{Y_{k}}{\sigma}-\left(1-W_{i}\right)^{1 / 2} Z\right\}
\end{aligned}
$$

Therefore, recalling the definition of $\tau$,

$$
\begin{aligned}
d_{W}\left(\frac{S}{\sigma}, \sum_{i=1}^{N} J_{i}\right)^{2} & \leq\left(E\left|\frac{S}{\sigma}-\sum_{i=1}^{N} J_{i}\right|\right)^{2} \leq E\left\{\left(\frac{S}{\sigma}-\sum_{i=1}^{N} J_{i}\right)^{2}\right\} \\
& =\sum_{i=1}^{N-1} E\left\{1\{\tau=i\}\left\{\sum_{k=i+1}^{N} \frac{Y_{k}}{\sigma}-\left(1-W_{i}\right)^{1 / 2} Z\right\}^{2}\right\} \\
& =\sum_{i=1}^{N-1} E\left\{1\{\tau=i\}\left\{\sum_{k=i+1}^{N} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)+1-W_{i}\right\}\right\} \\
& \leq \sum_{i=1}^{N-1} E\left\{1\{\tau=i\}\left\{\sum_{k=i+2}^{N} E\left(Y_{k}^{2} / \sigma^{2} \mid \mathcal{F}_{k-1}\right)+2 E\left(Y_{i+1}^{2} / \sigma^{2} \mid \mathcal{F}_{i}\right)\right\}\right\} \\
& \leq \sum_{i=1}^{N-1} E\left\{1\{\tau=i\}\left\{V^{2} / \sigma^{2}-1+2 \gamma^{2}\right\}\right\} \leq E\left|V^{2} / \sigma^{2}-1\right|+2 \gamma^{2} \\
& \leq 4 \gamma+2 \gamma^{2}
\end{aligned}
$$

where the last inequality is because of Lemma 10 . Since we assumed $\gamma \leq 1$, we obtain

$$
d_{W}\left(\frac{S}{\sigma}, \sum_{i=1}^{N} J_{i}\right) \leq \sqrt{6 \gamma}
$$

Finally, using Lemma 10 again, one obtains

$$
d_{W}\left(\sum_{i=1}^{N} J_{i}, \sum_{i=1}^{N+1} J_{i}\right) \leq E\left|J_{N+1}\right| \leq E\left\{\left|\frac{V^{2}}{\sigma^{2}}-1\right|^{1 / 2}\right\} \leq E\left\{\left(\frac{V^{2}}{\sigma^{2}}-1\right)^{2}\right\}^{1 / 4} \leq 2 \sqrt{\gamma}
$$

Collecting all these facts together yields, using again $\gamma \leq 1$,

$$
\begin{aligned}
d_{W}\left(\frac{S}{\sigma}, Z\right) & \leq d_{W}\left(\frac{S}{\sigma}, \sum_{i=1}^{N} J_{i}\right)+d_{W}\left(\sum_{i=1}^{N} J_{i}, \sum_{i=1}^{N+1} J_{i}\right)+d_{W}\left(\sum_{i=1}^{N+1} J_{i}, Z\right) \\
& \leq \sqrt{6 \gamma}+2 \sqrt{\gamma}+10 \gamma^{1 / 3} \leq 15 \gamma^{1 / 3}
\end{aligned}
$$

This concludes the proof.

Remark 12. If we do not care about the value of the constant in the estimate, the proof of Lemma 11 could be shortened by exploiting a result by Fan and Ma [12]; this result, however, does not provide explicit values of the majorizing constants. We also note that, under the conditions of Lemma 11, Heyde-Brown's inequality [14] yields

$$
d_{K}\left(\frac{S}{\sigma}, Z\right) \leq b\left\{E\left(\left(\frac{V^{2}}{\sigma^{2}}-1\right)^{2}\right)+\frac{1}{\sigma^{4}} \sum_{i=1}^{N} E Y_{i}^{4}\right\}^{1 / 5}
$$

for some constant $b$ independent of $N$. By Lemmas 2 and 10 , this implies

$$
d_{W}\left(\frac{S}{\sigma}, Z\right) \leq 4 \sqrt{d_{K}\left(\frac{S}{\sigma}, Z\right)} \leq 4 \sqrt{b}\left\{16 \gamma^{2}+\frac{\gamma^{2}}{\sigma^{2}} \sum_{i=1}^{N} E Y_{i}^{2}\right\}^{1 / 10}=4 \sqrt{b} 17^{1 / 10} \gamma^{1 / 5}
$$

Hence, in this case, Lemma 11 works better than Heyde-Brown's inequality to estimate $d_{W}(S / \sigma, Z)$.

Recall $L(c)$ defined in Theorem 6.
Lemma 13. Letting $\sigma_{c}^{2}=\operatorname{Var}\left(\sum_{i=1}^{N} \frac{X_{i}}{\sigma} 1\left\{\left|X_{i}\right| \leq c \sigma\right\}\right)$, we have

$$
\left|\sigma_{c}-1\right| \leq\left|\sigma_{c}^{2}-1\right| \leq 13 L(c) \quad \text { for all } c>0
$$

Proof. Fix $c>0$ and define

$$
A_{i}=\left\{\left|X_{i}\right|>c \sigma\right\}, \quad T_{i}=\frac{X_{i}}{\sigma} 1_{A_{i}}-E\left(\frac{X_{i}}{\sigma} 1_{A_{i}}\right), \quad V_{i}=\frac{X_{i}}{\sigma} 1_{A_{i}^{c}}-E\left(\frac{X_{i}}{\sigma} 1_{A_{i}^{c}}\right)
$$

On noting that $\sigma_{c}^{2}=\operatorname{Var}\left(\sum_{i=1}^{N} V_{i}\right)$, one obtains

$$
1=\operatorname{Var}\left(\sum_{i=1}^{N}\left(T_{i}+V_{i}\right)\right)=\operatorname{Var}\left(\sum_{i=1}^{N} T_{i}\right)+\sigma_{c}^{2}+2 \operatorname{Cov}\left(\sum_{i=1}^{N} T_{i}, \sum_{i=1}^{N} V_{i}\right)
$$

Since $\left(X_{1}, \ldots, X_{N}\right)$ is 1-dependent, it follows that

$$
\begin{aligned}
\left|\sigma_{c}^{2}-1\right| \leq & \operatorname{Var}\left(\sum_{i=1}^{N} T_{i}\right)+2\left|\operatorname{Cov}\left(\sum_{i=1}^{N} T_{i}, \sum_{i=1}^{N} V_{i}\right)\right| \\
= & \operatorname{Var}\left(\sum_{i=1}^{N} T_{i}\right)+2 \mid \sum_{i=1}^{N} \operatorname{Cov}\left(T_{i}, V_{i}\right) \\
& +\sum_{i=1}^{N-1} \operatorname{Cov}\left(T_{i}, V_{i+1}\right)+\sum_{i=2}^{N} \operatorname{Cov}\left(T_{i}, V_{i-1}\right) \mid
\end{aligned}
$$

Moreover,
(6) $\quad \operatorname{Var}\left(\sum_{i=1}^{N} T_{i}\right)=\sum_{i=1}^{N} \operatorname{Var}\left(T_{i}\right)+2 \sum_{i=1}^{N-1} \operatorname{Cov}\left(T_{i}, T_{i+1}\right)$

$$
\leq \sum_{i=1}^{N} \operatorname{Var}\left(T_{i}\right)+\sum_{i=1}^{N-1}\left(\operatorname{Var}\left(T_{i}\right)+\operatorname{Var}\left(T_{i+1}\right)\right) \leq 3 L(c)
$$

Similarly,

$$
\operatorname{Cov}\left(T_{i}, V_{i}\right)=-E\left(\frac{X_{i}}{\sigma} 1_{A_{i}}\right) E\left(\frac{X_{i}}{\sigma} 1_{A_{i}^{c}}\right)=E\left(\frac{X_{i}}{\sigma} 1_{A_{i}}\right)^{2} \leq E\left(\frac{X_{i}^{2}}{\sigma^{2}} 1_{A_{i}}\right)
$$

and

$$
\begin{aligned}
\left|\operatorname{Cov}\left(T_{i}, V_{i-1}\right)\right| & \leq E\left(\frac{\left|X_{i} X_{i-1}\right|}{\sigma^{2}} 1_{A_{i}} 1_{A_{i-1}^{c}}\right)+E\left(\frac{\left|X_{i}\right|}{\sigma} 1_{A_{i}}\right) E\left(\frac{\left|X_{i-1}\right|}{\sigma} 1_{A_{i-1}^{c}}\right) \\
& \leq 2 c E\left(\frac{\left|X_{i}\right|}{\sigma} 1_{A_{i}}\right) \leq 2 E\left(\frac{X_{i}^{2}}{\sigma^{2}} 1_{A_{i}}\right)
\end{aligned}
$$

where the last inequality is because

$$
\frac{c\left|X_{i}\right|}{\sigma} 1_{A_{i}} \leq \frac{\left|X_{i}^{2}\right|}{\sigma^{2}} 1_{A_{i}}
$$

By the same argument, $\left|\operatorname{Cov}\left(T_{i}, V_{i+1}\right)\right| \leq 2 \sigma^{-2} E\left(X_{i}^{2} 1_{A_{i}}\right)$. Collecting all these facts together, one finally obtains

$$
\left|\sigma_{c}^{2}-1\right| \leq 3 L(c)+10 \sum_{i=1}^{N} E\left(\frac{X_{i}^{2}}{\sigma^{2}} 1_{A_{i}}\right)=13 L(c)
$$

This completes the proof, since obviously $\left|\sigma_{c}-1\right| \leq\left|\sigma_{c}^{2}-1\right|$.
Having proved the previous lemmas, we are now ready to attack Theorem 6.

Proof of Theorem 6. Fix $c>0$. We have to show that

$$
d_{W}\left(\frac{S}{\sigma}, Z\right) \leq 30\left\{c^{1 / 3}+6 L(c)^{1 / 2}\right\}
$$

Since $d_{W}(S / \sigma, Z) \leq \sqrt{2}$, this inequality is trivially true if $L(c) \geq 1 / 100$ or if $c \geq 1$. Hence, it can be assumed $L(c)<1 / 100$ and $c<1$. Then, Lemma 13 implies $\sigma_{c}>0$.

Define $T_{i}$ and $V_{i}$ as in the proof of Lemma 13. Then $\left|V_{i}\right| \leq 2 c$ for every $i$, and thus $\left(V_{1}, \ldots, V_{N}\right)$ satisfies the conditions of Lemma 11 with $\sigma$ replaced by $\sigma_{c}$ and $\gamma=6 c / \sigma_{c}$. Hence,

$$
d_{W}\left(\frac{\sum_{i=1}^{N} V_{i}}{\sigma_{c}}, Z\right) \leq 15\left(6 c / \sigma_{c}\right)^{1 / 3}
$$

Now, recall from (6) that $\operatorname{Var}\left(\sum_{i=1}^{N} T_{i}\right) \leq 3 L(c)$. Hence, using Lemma 13 again, and the assumptions $L(c)<1$ and $c<1$,

$$
\begin{aligned}
d_{W}\left(\frac{S}{\sigma}, Z\right) & \leq d_{W}\left(\frac{S}{\sigma}, \sum_{i=1}^{N} V_{i}\right)+d_{W}\left(\sum_{i=1}^{N} V_{i}, \sigma_{c} Z\right)+d_{W}\left(\sigma_{c} Z, Z\right) \\
& \leq E\left|\frac{S}{\sigma}-\sum_{i=1}^{N} V_{i}\right|+\sigma_{c} d_{W}\left(\frac{\sum_{i=1}^{N} V_{i}}{\sigma_{c}}, Z\right)+\left|\sigma_{c}-1\right| \\
& \leq \sqrt{\operatorname{Var}\left(\sum_{i=1}^{N} T_{i}\right)+15\left(6 c \sigma_{c}^{2}\right)^{1 / 3}+13 L(c)} \\
& \leq \sqrt{3 L(c)}+15(6 c)^{1 / 3}(1+13 L(c))^{2 / 3}+13 L(c) \\
& \leq(\sqrt{3}+13) L(c)^{1 / 2}+15(6 c)^{1 / 3}\left(1+(13 L(c))^{2 / 3}\right) \\
& \leq 15(6 c)^{1 / 3}+\left(\sqrt{3}+13+15 \cdot 6^{1 / 3} \cdot(13)^{2 / 3}\right) L(c)^{1 / 2} \\
& \leq 30 c^{1 / 3}+170 L(c)^{1 / 2}
\end{aligned}
$$

This concludes the proof of Theorem 6.

## 4. Total variation distance and rate of convergence

Theorems 3 and 4 immediately imply the following result.
Theorem 14. Let $\phi_{n}$ be the characteristic function of $S_{n} / \sigma_{n}$ and

$$
l_{n}=2 \int_{0}^{\infty} t\left|\phi_{n}(t)\right| d t
$$

If conditions (1)-(2) hold, then
$d_{T V}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq \sqrt{120}\left\{c^{1 / 3}+12 U_{n}(c / 2)^{1 / 2}\right\}^{1 / 2}+30^{1 / 3} l_{n}^{2 / 3}\left\{c^{1 / 3}+12 U_{n}(c / 2)^{1 / 2}\right\}^{1 / 3}$ for all $n \geq 1$ and $c>0$, where $Z$ is a standard normal random variable.

Proof. First apply Theorem 3, with $V=1$ and $X_{n}=\frac{S_{n}}{\sigma_{n}}$, and then use Theorem 4.
Obviously, Theorem 14 is non-trivial only if $l_{n}<\infty$. In this case, the probability distribution of $S_{n}$ is absolutely continuous. An useful special case is when conditions (1)-(2) hold together with (4) (as in Corollary 5). Then, by taking $c=2 m_{n} \gamma_{n}$ so that $U_{n}(c / 2)=0$, Theorem 14 yields

$$
d_{T V}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq \sqrt{120}\left(2 m_{n} \gamma_{n}\right)^{1 / 6}+30^{1 / 3} l_{n}^{2 / 3}\left(2 m_{n} \gamma_{n}\right)^{1 / 9}
$$

Sometimes, this inequality allows to obtain a CLT in total variation distance; see Example 17 below.

We next discuss the convergence rate provided by Theorem 4 and we compare it with some existing results.

A first remark is that Theorem 4 is calibrated to the dependence case, and that it is not optimal in the independence case. To see this, it suffices to recall that we assume $m_{n} \geq 1$ for all $n$. If $X_{n 1}, \ldots, X_{n N_{n}}$ are independent, the best one can do is to let $m_{n}=1$, but this choice of $m_{n}$ is not efficient as is shown by the following example.

Example 15. Suppose $X_{n 1}, \ldots, X_{n N_{n}}$ are independent and conditions (2) and (4) hold. Define $m_{n}=1$ for all $n$. Then, $U_{n}\left(\gamma_{n}\right)=0$ and Theorem 4 (or Corollary 5) yields $d_{W}\left(S_{n} / \sigma_{n}, Z\right) \leq 30\left(2 \gamma_{n}\right)^{1 / 3}$. However, the Bikelis nonuniform inequality yields

$$
\left|P\left(S_{n} / \sigma_{n} \leq t\right)-P(Z \leq t)\right| \leq \frac{b}{(1+|t|)^{3}} \sum_{i=1}^{N_{n}} E\left\{\frac{\left|X_{n, i}\right|^{3}}{\sigma_{n}^{3}}\right\} \leq \frac{b \gamma_{n}}{(1+|t|)^{3}}
$$

for all $t \in \mathbb{R}$ and some universal constant $b$; see e.g. [9, p. 659]. Hence,

$$
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right)=\int_{-\infty}^{\infty}\left|P\left(S_{n} / \sigma_{n} \leq t\right)-P(Z \leq t)\right| d t \leq \int_{-\infty}^{\infty} \frac{b \gamma_{n}}{(1+|t|)^{3}} d t=b \gamma_{n}
$$

Leaving independence aside, a recent result to be mentioned is [10, Corollary 4.3] by Dedecker, Merlevede and Rio. This result applies to sequences of random variables and requires a certain mixing condition (denoted by $\left(H_{1}\right)$ ) which is automatically true when $m_{n}=m$ for all $n$. In this case, under conditions (2) and (4), one obtains

$$
\begin{equation*}
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq b \gamma_{n}\left(1+c_{n} \log \left(1+c_{n} \sigma_{n}^{2}\right)\right) \tag{7}
\end{equation*}
$$

where $b$ and $c_{n}$ are suitable constants with $b$ independent of $n$. Among other conditions, the $c_{n}$ must satisfy

$$
c_{n} \sigma_{n}^{2} \geq \sum_{i=1}^{N_{n}} E X_{n, i}^{2}
$$

Inequality (7) is actually sharp. However, if compared with Theorem 4, it has three drawbacks. First, unlike Theorem 4, it requires condition (4). Secondly, the mixing condition $\left(H_{1}\right)$ is not easily verified unless $m_{n}=m$ for all $n$. Thirdly, as seen in the next example, even if (4) holds and $m_{n}=m$ for all $n$, it may be that

$$
\gamma_{n} \rightarrow 0 \quad \text { but } \quad \gamma_{n} c_{n} \log \left(1+c_{n} \sigma_{n}^{2}\right) \rightarrow \infty \quad \text { as } n \rightarrow \infty .
$$

In such situations, Theorem 4 works while inequality (7) does not.
Example 16. Let $\left(a_{n}\right)$ be a sequence of numbers in $(0,1)$ such that $\lim _{n} a_{n}=0$. Let $\left(T_{i}: i \geq 0\right)$ and ( $\left.V_{n, i}: n \geq 1,1 \leq i \leq n\right)$ be two independent collections of real random variables. Suppose $\left(T_{i}\right)$ is i.i.d. with $P\left(T_{0}= \pm 1\right)=1 / 2$ and $V_{n, 1}, \ldots, V_{n, n}$ are i.i.d. with $V_{n, 1}$ uniformly distributed on the set $\left(-1,-1+a_{n}\right) \cup\left(1-a_{n}, 1\right)$.

Fix a constant $\alpha \in(0,1 / 3)$ and define $N_{n}=n$ and

$$
X_{n, i}=n^{-1 / 2} V_{n, i}+n^{-\alpha}\left(T_{i}-T_{i-1}\right)
$$

for $i=1, \ldots, n$. The array $\left(X_{n, i}\right)$ is centered and 1-dependent (namely, $m_{n}=1$ for all $n$ ). In addition, $S_{n}=n^{-1 / 2} \sum_{i=1}^{n} V_{n, i}+n^{-\alpha}\left(T_{n}-T_{0}\right)$ and

$$
\sigma_{n}^{2}=E V_{n, 1}^{2}+2 n^{-2 \alpha}, \quad \sum_{i=1}^{n} E X_{n, i}^{2}=E V_{n, 1}^{2}+2 n^{1-2 \alpha}
$$

Since $\lim _{n} \sigma_{n}^{2}=\lim _{n} E V_{n, 1}^{2}=1$, one obtains

$$
\max _{i} \frac{\left|X_{n, i}\right|}{\sigma_{n}} \leq \frac{n^{-1 / 2}+2 n^{-\alpha}}{\sigma_{n}} \leq \frac{3 n^{-\alpha}}{\sigma_{n}}<4 n^{-\alpha} \quad \text { for large } n
$$

Hence, for large $n$, condition (4) holds with $\gamma_{n}=4 n^{-\alpha}$. Consequently, Corollary 5 yields

$$
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 60 n^{-\alpha / 3} \quad \text { for large } n
$$

However,

$$
\begin{aligned}
4 n^{-\alpha} c_{n} \log \left(1+c_{n} \sigma_{n}^{2}\right) & \geq 4 n^{-\alpha} \frac{1}{\sigma_{n}^{2}} \sum_{i=1}^{n} E X_{n, i}^{2} \log \left(1+\sum_{i=1}^{n} E X_{n, i}^{2}\right) \\
& \geq 4(1-2 \alpha) \frac{n^{1-3 \alpha}}{\sigma_{n}^{2}} \log n \longrightarrow \infty
\end{aligned}
$$

In addition to [10, Corollary 4.3], there are some other estimates of $d_{W}\left(S_{n} / \sigma_{n}, Z\right)$. Without any claim of exhaustivity, we mention Fan and Ma [12], Röllin [21] and Van Dung, Son and Tien [26] (Röllin's result has been used for proving Lemma 11). There are also a number of estimates of $d_{K}\left(S_{n} / \sigma_{n}, Z\right)$ which, through Lemma 2, can be turned into upper bounds for $d_{W}\left(S_{n} / \sigma_{n}, Z\right)$; see [10], [12] and references therein. However, to our knowledge, none of these estimates implies Theorem 4. Typically, they require further conditions (in addition to (1)-(2)) and/or they yield a worse convergence rate; see e.g. Remark 12 and Example 16. This is the current state of the art. Our conjecture is that, under conditions (1)-(2) and possibly (4), the rate of Theorem 4 can be improved. To this end, one possibility could be using an upper bound provided by Haeusler and Joos [13] in the martingale CLT. Whether the rate of Theorem 4 can be improved, however, is currently an open problem.

## 5. FURTHER EXAMPLES AND APPLICATIONS

To illustrate the results above, we give some applications of Theorems 4 and 14. As usual, $Z$ denotes a standard normal random variable. We begin with a CLT in total variation distance.

Example 17. Let $\left(X_{n, i}\right)$ and $\left(V_{n, i}\right)$ be as in Example 16. Denote by $\psi_{n}$ the characteristic function of $\sum_{i=1}^{n} V_{n, i}$. Then, for each $t \in \mathbb{R}$,

$$
\begin{gathered}
\psi_{n}(t)=\left(\frac{1}{a_{n}} \int_{1-a_{n}}^{1} \cos (t x) d x\right)^{n} \quad \text { and } \\
\left|\phi_{n}(t)\right| \leq\left|\psi_{n}\left[t\left(n \sigma_{n}^{2}\right)^{-1 / 2}\right]\right|=\left|\frac{1}{a_{n}} \int_{1-a_{n}}^{1} \cos \left[t\left(n \sigma_{n}^{2}\right)^{-1 / 2} x\right] d x\right|^{n} .
\end{gathered}
$$

After some algebra (we omit the explicit calculations) it can be shown that

$$
l_{n}=2 \int_{0}^{\infty} t\left|\phi_{n}(t)\right| d t \leq b a_{n}^{-2}
$$

for some constant $b$ independent of $n$. Recalling that $m_{n}=1$ and $\gamma_{n}=4 n^{-\alpha}$ for large $n$ (see Example 16), Theorem 14 yields (taking again $c=2 m_{n} \gamma_{n}=8 n^{-\alpha}$ )

$$
\begin{aligned}
d_{T V}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) & \leq \sqrt{120}\left(2 m_{n} \gamma_{n}\right)^{1 / 6}+30^{1 / 3} l_{n}^{2 / 3}\left(2 m_{n} \gamma_{n}\right)^{1 / 9} \\
& \leq \sqrt{120} 8^{1 / 6} n^{-\alpha / 6}+30^{1 / 3} b^{2 / 3} 8^{1 / 9}\left(a_{n}^{4} n^{\alpha / 3}\right)^{-1 / 3}
\end{aligned}
$$

for large $n$. Therefore, the probability distribution of $S_{n} / \sigma_{n}$ converges to the standard normal law, in total variation distance, provided $a_{n}^{4} n^{\alpha / 3} \rightarrow \infty$.

The next two examples are connected to the Breuer-Major theorem [4] (henceforth, BMT). In both the examples, $g: \mathbb{R} \rightarrow \mathbb{R}$ is a Borel function with Hermite degree $d \geq 1$. This means that $E\left(g^{2}(Z)\right)<\infty$ with a series expansion of the type

$$
g=\sum_{j=d}^{\infty} c_{j} H_{j}, \quad c_{d} \neq 0
$$

where $H_{j}$ is the Hermite polynomial of degree $j$.
Example 18. There is recently a certain interest on the asymptotic behavior of

$$
Q_{n}=\frac{\sum_{i=0}^{n-1} g\left(Y_{i}\right)}{\sqrt{\operatorname{Var}\left[\sum_{i=0}^{n-1} g\left(Y_{i}\right)\right]}}
$$

where ( $Y_{n}: n \geq 0$ ) is a stationary Gaussian sequence of standard normal random variables; see e.g. [5], [16] and references therein. Because of BMT, $Q_{n} \xrightarrow{\text { dist }} Z$ provided $\sum_{n}\left|E\left(Y_{n} Y_{0}\right)\right|^{d}<\infty$ (recall that $d \geq 1$ is the Hermite degree of $g$ ). To obtain a quantitative estimate of $d_{W}\left(Q_{n}, Z\right)$, some further conditions are needed. Essentially, $g$ must belong to a suitable Sobolev space.

At the price of assuming $\left(m_{n}\right)$-dependence, Theorem 4 allows to improve BMT. Among other things, the stationarity assumption is dropped, sequences are replaced by arrays, and the conditions on $g$ are much more general.

For each $n \geq 1$, suppose

$$
\left(X_{n, 1}, \ldots, X_{n, N_{n}}\right) \text { is Gaussian, } \quad X_{n, i} \sim \mathcal{N}(0,1) \text { for all } i,
$$ and $E\left(X_{n, i} X_{n, j}\right)=0$ whenever $|i-j|>m_{n}$.

Moreover, fix any Borel function $g_{n}: \mathbb{R} \rightarrow \mathbb{R}$ such that $E\left(g_{n}(Z)\right)=0$ and $E\left(g_{n}^{2}(Z)\right)<\infty$ and suppose

$$
\sigma_{n}^{2}:=\operatorname{Var}\left[\sum_{i=1}^{N_{n}} g_{i}\left(X_{n, i}\right)\right]>0
$$

Then, Theorem 4 yields

$$
d_{W}\left(Q_{n}^{*}, Z\right) \leq 30 c^{1 / 3}+\frac{360 \sqrt{m_{n}}}{\sigma_{n}}\left(\sum_{i=1}^{N_{n}} E\left[g_{i}^{2}(Z) 1\left\{\left|g_{i}(Z)\right|>c \sigma_{n} / 2 m_{n}\right\}\right]\right)^{1 / 2}
$$

for all $n \geq 1$ and $c>0$, where

$$
Q_{n}^{*}=\frac{1}{\sigma_{n}} \sum_{i=1}^{N_{n}} g_{i}\left(X_{n, i}\right)
$$

This upper bound is effective if the sequence $\left(g_{n}^{2}(Z): n \geq 1\right)$ is uniformly integrable. Note also that, if $g_{n}(Z) \in L_{\infty}$ for all $n$, Corollary 5 yields

$$
d_{W}\left(Q_{n}^{*}, Z\right) \leq 40\left(\frac{m_{n}}{\sigma_{n}} \max _{1 \leq i \leq N_{n}}\left\|g_{i}(Z)\right\|_{\infty}\right)^{1 / 3}
$$

Example 19. Let $Y=\left(Y_{t}: t \geq 0\right)$ be a real cadlag process. To begin with, suppose $Y$ is stationary, Gaussian, $Y_{0} \sim \mathcal{N}(0,1)$, and define

$$
Z_{\epsilon}(t)=\sqrt{\epsilon} \int_{0}^{t / \epsilon} g\left(Y_{s}\right) d s \quad \text { for all } \epsilon>0 \text { and } t \geq 0
$$

If $\int\left|E\left(Y_{t} Y_{0}\right)\right|^{d} d t<\infty$ then, as $\epsilon \rightarrow 0$, the finite dimensional distributions of $Z_{\epsilon}$ converge weakly to those of $\sigma W$, where $\sigma$ is an explicit constant and $W$ a standard Brownian motion. This is BMT in continuous-time. By a result in [5], if $E\left(|g(Z)|^{p}\right)<\infty$ for some $p>2$, one also obtains $Z_{\epsilon} \xrightarrow{\text { dist }} \sigma W$ in the space $C([0, \infty), \mathbb{R})$ (equipped with the topology of uniform convergence on compacta).

Next, suppose $Y$ is a Levy process. Let $f: \mathbb{R} \rightarrow \mathbb{R}$ be a continuous function and $\lambda:(0, \infty) \rightarrow(0, \infty)$ a non-increasing function such that

$$
a:=\sup |f|<\infty \quad \text { and } \quad b:=\sup \lambda<\infty .
$$

Roughly speaking, $\lambda$ should be regarded as a delay in observing $Y$. Given $\epsilon>0$ and $s \geq \lambda(\epsilon)$, the actual value of $Y$ at time $s-\lambda(\epsilon)$ is not $Y_{s-\lambda(\epsilon)}$ but $Y_{s}$. Hence, $Y_{s}-Y_{s-\lambda(\epsilon)}$ may be seen as an observation error. Let

$$
Z_{\epsilon}^{*}(t)=\sqrt{\epsilon} \int_{0}^{t / \epsilon} f\left(Y_{s}-Y_{(s-\lambda(\epsilon))^{+}}\right) d s
$$

In order to apply Theorem 4 to $Z_{\epsilon}^{*}$, fix $t>0$ and define

$$
n_{\epsilon}(t)=\left\lfloor\frac{t}{\epsilon \lambda(\epsilon)}\right\rfloor-1 \quad \text { and } \quad I_{t}=\left\{\epsilon>0: n_{\epsilon}(t) \geq 1\right\} .
$$

For $\epsilon \in I_{t}$ and $i \geq 1$, define also

$$
X_{\epsilon, i}=\sqrt{\epsilon} \int_{i \lambda(\epsilon)}^{(i+1) \lambda(\epsilon)} f\left(Y_{s}-Y_{s-\lambda(\epsilon)}\right) d s, \quad V_{\epsilon}(t)=\sum_{i=1}^{n_{\epsilon}(t)} X_{\epsilon, i}, \quad \sigma_{\epsilon}^{2}(t)=E\left(V_{\epsilon}^{2}(t)\right) .
$$

Assume $E\left[f\left(Y_{\lambda(\epsilon)}\right)\right]=0$ (for example, this holds if $f$ is odd and $Y_{\lambda(\epsilon)}$ is symmetric), and also $\sigma_{\epsilon}^{2}(t)>0$ for $\epsilon \in I_{t}$. Then, $E\left[f\left(Y_{s}-Y_{s-\lambda(\epsilon)}\right)\right]=E\left[f\left(Y_{\lambda(\epsilon)}\right)\right]=0$ for $s \geq \lambda(\epsilon)$, so that $E\left(X_{\epsilon, i}\right)=0$, and since the array

$$
\left(X_{\epsilon, i}: \epsilon \in I_{t}, i=1, \ldots, n_{\epsilon}(t)\right)
$$

is 1-dependent, Theorem 4 yields, for any $c>0$,

$$
d_{W}\left(\frac{V_{\epsilon}(t)}{\sigma_{\epsilon}(t)}, Z\right) \leq 30 c^{1 / 3}+360 \sqrt{\frac{n_{\epsilon}(t)}{\sigma_{\epsilon}^{2}(t)} E\left[X_{\epsilon, 1}^{2} 1\left\{\left|X_{\epsilon, 1}\right|>c \sigma_{\epsilon}(t) / 2\right\}\right]}
$$

Moreover, since $\left|X_{\epsilon, i}\right| \leq a b \sqrt{\epsilon}$, Corollary 5 yields

$$
d_{W}\left(\frac{V_{\epsilon}(t)}{\sigma_{\epsilon}(t)}, Z\right) \leq 30\left(\frac{2 a b \sqrt{\epsilon}}{\sigma_{\epsilon}(t)}\right)^{1 / 3}
$$

Since $f$ is continuous and the $Y$-paths are cadlag, one also obtains

$$
\lim _{\epsilon \rightarrow 0} \sigma_{\epsilon}^{2}(t)=\lim _{\epsilon \rightarrow 0}\left\{n_{\epsilon}(t) E\left(X_{\epsilon, 1}^{2}\right)+2\left(n_{\epsilon}(t)-1\right) E\left(X_{\epsilon, 1} X_{\epsilon, 2}\right)\right\}=\frac{t r}{b}
$$

where
$r=E\left[\left(\int_{b}^{2 b} f\left(Y_{s}-Y_{s-b}\right) d s\right)^{2}\right]+2 E\left[\int_{b}^{2 b} f\left(Y_{s}-Y_{s-b}\right) d s \int_{2 b}^{3 b} f\left(Y_{s}-Y_{s-b}\right) d s\right]$.
Hence, if $r>0$, then $\lim _{\epsilon \rightarrow 0} d_{W}\left(\frac{V_{\epsilon}(t)}{\sigma_{\epsilon}(t)}, Z\right)=0$. Since

$$
\begin{equation*}
\left|Z_{\epsilon}^{*}(t)-V_{\epsilon}(t)\right| \leq 2 a b \sqrt{\epsilon}, \tag{8}
\end{equation*}
$$

it follows that

$$
Z_{\epsilon}^{*}(t) \xrightarrow{\text { dist }} \sqrt{\frac{t r}{b}} Z \sim \sqrt{\frac{r}{b}} W_{t}, \quad \text { as } \epsilon \rightarrow 0
$$

where $W$ is a standard Brownian motion. Moreover, with exactly the same argument, one also obtains

$$
\begin{equation*}
\left(Z_{\epsilon}^{*}\left(t_{1}\right), \ldots, Z_{\epsilon}^{*}\left(t_{k}\right)\right) \xrightarrow{\text { dist }} \sqrt{\frac{r}{b}}\left(W_{t_{1}}, \ldots, W_{t_{k}}\right) \tag{9}
\end{equation*}
$$

for all $k \geq 1$ and all $0 \leq t_{1}<t_{2}<\ldots<t_{k}$. Finally,

$$
\begin{equation*}
Z_{\epsilon}^{*} \xrightarrow{\text { dist }} \sqrt{\frac{r}{b}} W \quad \text { in the space } C([0, \infty), \mathbb{R}) \tag{10}
\end{equation*}
$$

We just give a sketch of the proof of (10). Let $D$ be the space of real cadlag functions on $[0, \infty)$ endowed with the Skorohod topology. First, one proves that

$$
E\left[\left(V_{\epsilon}(s)-V_{\epsilon}(t)\right)^{4}\right] \leq \alpha \epsilon^{2}\left(\left\lfloor\frac{t}{\epsilon \lambda(\epsilon)}\right\rfloor-\left\lfloor\frac{s}{\epsilon \lambda(\epsilon)}\right\rfloor\right)^{2}
$$

for all $0 \leq s<t$, all $\epsilon>0$, and some constant $\alpha$. Based on [16, Lemma 3.1], this and the finite-dimensional convergence following from (8) and (9) imply $V_{\epsilon} \xrightarrow{\text { dist }} \sqrt{\frac{r}{b}} W$ in the space $D$. Because of (8), one also obtains $Z_{\epsilon}^{*} \xrightarrow{\text { dist }} \sqrt{\frac{\tau}{b}} W$ in the space $D$. Finally, (10) follows since $Z_{\epsilon}^{*}$ and $\sqrt{\frac{r}{b}} W$ have continuous paths.

Our last example may be useful as regards the CLT for high dimensional data.

Example 20. For $i=1, \ldots, N$, let

$$
X_{i}=\left(X_{i, 1}, \ldots, X_{i, p}\right)
$$

be a $p$-dimensional random vector. Suppose:
(i) The vectors $X_{1}, \ldots, X_{N}$ are $m$-dependent and $X_{i, j} \in L_{\infty}$ for all $i, j$;
(ii) $E\left(X_{i, j}\right)=0$ and $E\left(X_{i, j} X_{h, k}\right)=0$ for all $i, j, h, k$ with $j \neq k$;
(iii) $\sigma_{j}^{2}=E\left[\left(\sum_{i=1}^{N} X_{i, j}\right)^{2}\right]>0$ for all $j=1, \ldots, p$.

Define

$$
Y=\sum_{i=1}^{N} \sum_{j=1}^{p} \frac{a_{j} X_{i, j}}{\sigma_{j}}
$$

where the $a_{j}$ are constants satisfying $\sum_{j=1}^{p} a_{j}^{2}=1$, and note that $\operatorname{Var}(Y)=1$. Upper bounds for $d_{W}(Y, Z)$ allow to estimate the goodness of the normal approximation for the distribution of $Y$. For instance, they are involved in the study of the dependence graph of high-dimensional time series; see [6] and references therein. Under conditions (i)-(iii), Corollary 5 yields

$$
d_{W}(Y, Z) \leq 40\left(m \sqrt{p} \max _{i, j} \frac{\left\|X_{i, j}\right\|_{\infty}}{\sigma_{j}}\right)^{1 / 3}
$$

This can be compared to the related estimate in [6, Corollary 1] (which is for the Kolmogorov distance, and among other differences includes a different power $\mathrm{m}^{2 / 3}$ ).

## 6. Final comment: beyond $\left(m_{n}\right)$-dependence

We close with a result which enlarges the scope of Theorem 4. It is motivated by the following (natural) question. Let $\left(X_{n, i}\right)$ be an arbitrary array of real random variables. Under what conditions $\left(X_{n, i}\right)$ can be approximated by a $\left(m_{n}\right)$-dependent array? Sometimes, this approximation is possible. As suggested by an anonymous referee, for instance, it is actually possible if ( $X_{n, i}$ ) satisfies a suitable mixing condition or some form of physical dependence. Generally, however, the approximation of $\left(X_{n, i}\right)$ by a $\left(m_{n}\right)$-dependent array requires strong conditions. Therefore, we focus on a related problem, that is, we look for a version of Theorem 4 where ( $X_{n, i}$ ) is not required to be $\left(m_{n}\right)$-dependent. To this end, we need some notation. Define

$$
W_{n, i}=E\left(X_{n, i}+X_{n, i+1} \mid \mathcal{F}_{n, i}\right)-E\left(X_{n, i}+X_{n, i+1} \mid \mathcal{F}_{n, i-1}\right)
$$

where $\mathcal{F}_{n, i}=\sigma\left(X_{n, 1}, \ldots, X_{n, i}\right)$ and $\mathcal{F}_{n, 0}$ is the trivial $\sigma$-field. Define also
$\gamma_{n}=\frac{1}{\sigma_{n}} \max _{i}\left\|X_{n, i}\right\|_{\infty}, \quad a_{n}^{2}=E\left[\left(\sum_{i=2}^{N_{n}} E\left(X_{n, i} \mid \mathcal{F}_{n, i-2}\right)\right)^{2}\right], \quad w_{n}^{2}=\sum_{i=1}^{N_{n}-1} E\left(W_{n, i}^{2}\right)$.

## Proposition 21. Suppose:

- $\left(X_{n, i}\right)$ satisfies condition (2) and $X_{n, i} \in L_{\infty}$ for all $n$ and $i$;
- There are constants $\alpha$ and $\beta$ such that

$$
\sigma_{n} \leq \alpha w_{n} \quad \text { and } \quad\left|\sum_{1 \leq i<j<N_{n}} \operatorname{Cov}\left(W_{n, i}^{2}, W_{n, j}^{2}\right)\right| \leq \beta \gamma_{n}^{2} \sigma_{n}^{4}
$$

for all $n \geq 1$. Then, there is a constant $q$ (independent of $n$ ) such that

$$
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq q\left(\frac{a_{n}}{\sigma_{n}}+\gamma_{n}^{1 / 3}\right) \quad \text { for all } n \geq 1
$$

Proof. Letting
$A_{n}=\sum_{i=2}^{N_{n}} E\left(X_{n, i} \mid \mathcal{F}_{n, i-2}\right), \quad W_{n}=\sum_{i=1}^{N_{n}-1} W_{n, i}, \quad L_{n}=X_{n, N_{n}}-E\left(X_{n, N_{n}} \mid \mathcal{F}_{n, N_{n}-1}\right)$,
one obtains

$$
S_{n}=A_{n}+W_{n}+L_{n}
$$

Note also that ( $W_{n, i}: 1 \leq i<N_{n}$ ) is a martingale difference sequence, and thus

$$
E\left(W_{n}^{2}\right)=w_{n}^{2}
$$

Hence,

$$
\begin{aligned}
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) & \leq d_{W}\left(\frac{S_{n}}{\sigma_{n}}, \frac{A_{n}+W_{n}}{\sigma_{n}}\right)+d_{W}\left(\frac{A_{n}+W_{n}}{\sigma_{n}}, \frac{W_{n}}{\sigma_{n}}\right)+d_{W}\left(\frac{W_{n}}{\sigma_{n}}, \frac{W_{n}}{w_{n}}\right)+d_{W}\left(\frac{W_{n}}{w_{n}}, Z\right) \\
& \leq 2 \gamma_{n}+\frac{a_{n}}{\sigma_{n}}+\left|1-\frac{w_{n}}{\sigma_{n}}\right|+d_{W}\left(\frac{W_{n}}{w_{n}}, Z\right)
\end{aligned}
$$

Since $\left(W_{n, i}: 1 \leq i<N_{n}\right)$ is a martingale difference sequence and

$$
\max _{i}\left|W_{n, i}\right| \leq 4 \max _{i}\left\|X_{n, i}\right\|_{\infty} \leq 4 \sigma_{n} \gamma_{n} \leq 4 \alpha w_{n} \gamma_{n} \quad \text { a.s. }
$$

the arguments of Lemmas 10 and 11 can be applied to $Y_{i}=W_{n, i}$ (with $\sigma_{n}$ replaced by $\left.w_{n}\right)$. Therefore, $d_{W}\left(\frac{W_{n}}{w_{n}}, Z\right) \leq q^{*} \gamma_{n}^{1 / 3}$ for some constant $q^{*}$ that depends on $\alpha$ and $\beta$ (but nothing else). In addition,

$$
\begin{aligned}
\left|1-\frac{w_{n}^{2}}{\sigma_{n}^{2}}\right| & =\frac{1}{\sigma_{n}^{2}}\left|E\left[\left(A_{n}+W_{n}+L_{n}\right)^{2}\right]-E\left(W_{n}^{2}\right)\right| \\
& =\frac{1}{\sigma_{n}^{2}}\left|E\left[\left(A_{n}+L_{n}\right)^{2}\right]+2 E\left[W_{n}\left(A_{n}+L_{n}\right)\right]\right| \\
& \leq \frac{2}{\sigma_{n}^{2}}\left\{E\left(A_{n}^{2}\right)+E\left(L_{n}^{2}\right)+w_{n} \sqrt{E\left(A_{n}^{2}\right)}+w_{n} \sqrt{E\left(L_{n}^{2}\right)}\right\} \\
& =\frac{2}{\sigma_{n}^{2}}\left\{a_{n}^{2}+E\left(L_{n}^{2}\right)+w_{n}\left(a_{n}+\sqrt{E\left(L_{n}^{2}\right)}\right)\right\},
\end{aligned}
$$

so that

$$
\left|1-\frac{w_{n}}{\sigma_{n}}\right|=\frac{\left|1-\frac{w_{n}^{2}}{\sigma_{n}^{2}}\right|}{1+\frac{w_{n}}{\sigma_{n}}} \leq 2\left(\frac{a_{n}^{2}}{\sigma_{n}^{2}}+\frac{a_{n}}{\sigma_{n}}+4 \gamma_{n}^{2}+2 \gamma_{n}\right)
$$

Collecting all these facts together,

$$
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 3 \frac{a_{n}}{\sigma_{n}}+2 \frac{a_{n}^{2}}{\sigma_{n}^{2}}+8 \gamma_{n}^{2}+6 \gamma_{n}+q^{*} \gamma_{n}^{1 / 3}
$$

Hence, with $q=14+q^{*}$, if $\frac{a_{n}}{\sigma_{n}} \leq 1$ and $\gamma_{n} \leq 1$, one obtains

$$
\begin{equation*}
d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq 5 \frac{a_{n}}{\sigma_{n}}+\left(14+q^{*}\right) \gamma_{n}^{1 / 3} \leq q\left(\frac{a_{n}}{\sigma_{n}}+\gamma_{n}^{1 / 3}\right), \tag{11}
\end{equation*}
$$

and otherwise (11) is trivial since $d_{W}\left(\frac{S_{n}}{\sigma_{n}}, Z\right) \leq \sqrt{2}$ by Lemma 2 .
It is worth noting that Proposition 21 deviates from some analogous results available in the literature (such as [8] and [23]) for it does not require either stationaritymixing assumptions or martingale assumptions. Furthermore, Proposition 21 provides a quantitative bound as well.
