HOMOGENEOUS 1-BASED STRUCTURES AND INTERPRETABILITY IN RANDOM STRUCTURES

VERA KOPONEN

Abstract. Let \( V \) be a finite relational vocabulary in which no symbol has arity greater than 2. Let \( M \) be countable \( V \)-structure which is homogeneous, simple and 1-based. The first main result says that if \( M \) is, in addition, primitive, then it is strongly interpretable in a random structure. The second main result, which generalizes the first, implies (without the assumption on primitivity) that if \( M \) is “coordinate” by a set with SU-rank 1 and there is no definable (without parameters) nontrivial equivalence relation on \( M \) with only finite classes, then \( M \) is strongly interpretable in a random structure.

Keywords: model theory, homogeneous structure, simple theory, 1-based theory, random structure.

1. Introduction

A first-order structure \( M \) will be called homogeneous if it has a finite relational vocabulary and every isomorphism between finite substructures of \( M \) can be extended to an automorphism of \( M \). For surveys of homogeneous structures and their connections to other areas see [3, 5, 15, 26, 27]. Although there are \( 2^\omega \) countable nonisomorphic homogeneous structures for a vocabulary with only one binary relation symbol [16], it has been shown that in several cases, such as partial orders, undirected graphs, directed graphs and stable relational structures (with finite relational vocabulary), the countable homogeneous structures among them can be classified in a rather concrete way [5, 12, 13, 18, 21, 22, 23, 24, 28, 29]. The work on stable homogeneous structures together and on “geometric stability theory” (notably by Zilber [32]) was useful to reach a good understanding of \( \omega \)-categorical \( \omega \)-stable structures [7] and later of smoothly approximable structures [6, 19].

Stability theory was from the mid 90ies generalized to simplicity theory, where the class of simple theories is the largest class of complete theories \( T \) such that in every \( M \models T \) there is a symmetric “independence relation” on subsets of \( M \). The random graph (or Rado graph) is a standard example of a homogeneous simple structure (i.e. one which has simple theory) which is not stable, and the same is true of the “random structure” with respect to any finite relational vocabulary. Since the infinite countable stable homogeneous structures are classified [22], one may ask if it is possible to reach, if not a classification, at least some systematic understanding of (infinite countable) simple homogeneous structures. Besides the present work, [1, 20] and the dissertation of Aranda Lópes [2] the author is not aware of any results in this direction. The class of all simple homogeneous structures seems too wide to start with, so we focus on a subclass of it which seems easier to deal with. We consider homogeneous, simple and 1-based structures, where the property 1-based implies (for structures in general) that the independence relation behaves “nicely” (like in a vector space or random structure, for example). In fact, it follows from work of Macpherson [25] and De Piro and Kim [9] that every homogeneous, simple and 1-based structure has trivial dependence. If a homogeneous structure has only unary and binary relation symbols, then it is 1-based if and only if it has trivial dependence (see Definition 2.6 and Fact 2.7 below).
Moreover, we focus on binary homogeneous structures, where a structure is called binary if its vocabulary is finite, relational and has no symbol with arity greater than 2. This simplifies the situation because the “independence theorem” of simple theories has strong consequences in the context of binary structures. For example it follows, roughly speaking, that every $\emptyset$-definable set of SU-rank 1 (in the extension by imaginaries) is – when viewed as a “canonically embedded structure” – a reduct of a binary random structure. The working hypothesis is that countable, binary, homogeneous, simple and 1-based structures are sufficiently uncomplicated that it should be possible to work out some sort of rather explicit understanding of them. Moreover, the author does not know of any example of a homogeneous and simple structure which is not 1-based. Such an example, particularly a binary one, would probably shed light on the understanding of simple homogeneous structures. A proof that it does not exist would also be striking.

We say that a structure is primitive if there is no nontrivial equivalence relation on its universe which is definable without parameters. (Nontrivial means that there are at least two classes and at least one has more than one element.) It is easy to see that if $\mathcal{M}$ is homogeneous (and simple and 1-based) and nonprimitive, then the substructure on any equivalence class of the equivalence relation that witnesses nonprimitiveness is homogeneous (and simple and 1-based). So a good understanding of homogeneous simple structures requires an equally good understanding of primitive homogeneous simple structures. In particular we have the following problem, where the notion of a ‘binary random structure’ is explained in Section 2.4:

Is every countable, binary, homogeneous, primitive, simple and 1-based structure a random structure?

The problem is open also if we remove the assumptions about binarity and 1-basedness. Our first main result can be seen as an “approximate solution”:

**Theorem 1.1.** Suppose that $\mathcal{M}$ is a structure which is countable, binary, homogeneous, primitive, simple and 1-based. Then $\mathcal{M}$ is strongly interpretable in a binary random structure.

The notion strongly interpretable (Definition 2.14) implies the notion interpretable in its usual senses (e.g. [17, 25]). Hence Theorem 1.1 can be interpreted as saying that a countable, binary, homogeneous, primitive, simple and 1-based cannot be more complicated than a binary random structure. The theorem may also be of help to solve the problem stated above.

The second main result is a generalisation of the first one, but has a more complicated formulation, which is why we stated Theorem 1.1 first and not as a corollary of Theorem 1.2 below. Theorem 1.2 applies to some (but not all) nonprimitive binary homogeneous simple and 1-based structures. For example, let $\mathcal{R}$ be the random graph, let $\mathcal{M} = \mathcal{R}^2$ and let $\mathcal{M}$ be the structure with universe $\mathcal{M}$ that has a binary relation symbol $R_p$ for every 4-type over $\emptyset$ of $\mathcal{R}$ and where $R_p$ is interpreted as $\{(a,b),(a',b') : \mathcal{R} \models p(a,b,a',b')\}$. Then $\mathcal{M}$ satisfies the hypotheses of Theorem 1.2. (The same holds if $\mathcal{R}$ is any binary random structure and we consider ordered $k$-tuples for any fixed $k > 1$.) On the other hand if, for example, $\mathcal{M}$ is the structure with infinite countable universe, two equivalence relations $R_1, R_2$, such that $R_2$ refines $R_1$ by splitting each $R_1$-class into infinitely many infinite parts, then $\mathcal{M}$ does not have height 1, so Theorem 1.2 does not apply.\(^1\) The concept of ‘height’, appearing below, is given by Definition 2.8, and the notation $\mathcal{M}/\approx$ is explained in Definition 2.4:

**Theorem 1.2.** Suppose that $\mathcal{M}$ is a structure which is countable, binary, homogeneous, simple and 1-based with height 1. Let $\approx$ denote the equivalence relation $\text{acl}_\mathcal{M}(x) = \text{acl}_\mathcal{M}(y)$.

\(^1\)This structure has height 2 in the sense of [10]. It is of course a structure which is easy to understand. But examples with height 2 and the other properties of $\mathcal{M}$ can be more complicated.
acl\(\mathcal{M}(y)\)', where 'acl\(\mathcal{M}\)' denotes algebraic closure in \(\mathcal{M}\).

(i) Then there is a binary random structure \(\mathcal{R}\) such that \(\mathcal{M}/\approx\) is definable in \(\mathcal{R}^{eq}\).

(ii) If, in addition, the equivalence relation '\(\approx\) is trivial, then \(\mathcal{M}\) is strongly interpretable in a binary random structure.

The author hopes that this theorem can be generalised in a suitable way to 'height in a binary random structure.

One also needs to know what a canonically embedded structure \(\mathcal{G}\) in \(\mathcal{M}^{eq}\) may look like if its universe is a definable set with SU-rank 1. It turns out that if \(\mathcal{M}\) is countable, binary, homogeneous and simple with trivial dependence then \(\mathcal{G}\) is a reduct (Def. 2.12) of a binary random structure. This is proved in [1] and the result is refered to as Fact 2.13 below. The main technical result (besides Fact 2.13) is Lemma 3.9 which is proved in Section 4. The assumption that \(\mathcal{M}\) in Theorems 1.1 and 1.2 is binary is only used in the application of Fact 2.13 and in the proof of Lemma 3.9.

2. Preliminaries

The prerequisites of this article are more or less the same as those of [1]. We list, in this section, a number of definitions and facts, concerning homogeneous structures, \(\omega\)-categorical simple structures and imaginary elements, in order to make this article relatively self contained, but refer to [1] for further explanations.

2.1. General notation and terminology. We call a vocabulary (also called signature) relational if it only contains relation symbols. Given a finite relational vocabulary the maximal arity of it is the largest integer \(k\) such that some relation symbol of it has arity \(k\). If \(V\) is a finite vocabulary and the maximal arity is 2 then we call \(V\) binary (although it may contain unary relation symbols), and in this case a \(V\)-structure may be called a binary structure. We denote (first-order) structures by \(\mathcal{A}, \mathcal{B}, \ldots, \mathcal{M}, \mathcal{N}, \ldots\) and their respective universes by \(A, B, \ldots, M, N, \ldots\). Finite sequences (tuples) of elements of some structure (or set in general) will be denoted \(\bar{a}, \bar{b}, \ldots\), while \(a, b, \ldots\) usually denote elements from the universe of some structure. The notation \(\bar{a} \in A\) means that every element in the sequence \(\bar{a}\) belongs to \(A\). Sometimes we write \(\bar{a} \in A^n\) to show that the length of \(\bar{a}\), denoted \(|\bar{a}|\), is \(n\). The range of \(\bar{a}\), denoted \(\text{rng}(\bar{a})\), is the set of elements that occur in \(\bar{a}\). Notation regarding types, algebraic closure and definable closure is standard, where we may use a subscript or superscript to indicate which structure we have in mind.

A structure \(\mathcal{M}\) is called \(\omega\)-categorical, respectively simple, if its complete theory \(Th(\mathcal{M})\) has that property. (See [17] and [4, 31] for definitions.)

2.2. Homogeneous and \(\omega\)-categorical structures.

**Definition 2.1.** (i) Let \(V\) be a finite relational vocabulary and \(\mathcal{M}\) a \(V\)-structure. We call \(\mathcal{M}\) homogeneous if for all finite substructures \(\mathcal{A}\) and \(\mathcal{B}\) of \(\mathcal{M}\), every isomorphism from \(\mathcal{A}\) to \(\mathcal{B}\) can be extended to an automorphism of \(\mathcal{M}\).

(ii) We say that a structure \(\mathcal{M}\), with any vocabulary, is \(\omega\)-homogeneous if whenever \(n < \omega, a_1, \ldots, a_n, b_1, \ldots, b_n \in M\) and \(tp_{\mathcal{M}}(a_1, \ldots, a_n) = tp_{\mathcal{M}}(b_1, \ldots, b_n)\), then there is \(b_{n+1} \in M\) such that \(tp_{\mathcal{M}}(a_1, \ldots, a_{n+1}) = tp_{\mathcal{M}}(b_1, \ldots, b_{n+1})\).
For standard results about homogeneous structures we refer to (for example) [17, Sections 7.1 and 7.4]. We mainly use the following implications of homogeneity (or $\omega$-categoricity), which follow from Corollary 7.4.2 in [17] and from the well known characterization of $\omega$-categorical theories by Engeler, Ryll-Nardzewski and Svenonius:

**Fact 2.2.** (i) If $\mathcal{M}$ is $\omega$-categorical then it is $\omega$-homogeneous.
(ii) Suppose that $\mathcal{M}$ is countable and $\omega$-homogeneous. Then for all $0 < n < \omega$ and all $a_1, \ldots, a_n, b_1, \ldots, b_n \in M$ such that $\text{tp}_M(a_1, \ldots, a_n) = \text{tp}_M(b_1, \ldots, b_n)$, there is an automorphism $f$ of $\mathcal{M}$ such that $f(a_i) = b_i$ for every $i$.
(iii) Suppose that $\mathcal{M}$ is a countable $V$-structure where $V$ is a finite relational vocabulary. Then $\mathcal{M}$ is homogeneous if and only if $\mathcal{M}$ is $\omega$-categorical and has elimination of quantifiers.

2.3. Simple structures, imaginary elements, 1-basedness and triviality of dependence. We assume familiarity with imaginary elements and $\mathcal{M}^{eq}$, defined in [17, 30] for example, and with basic simplicity theory, as found in [4, 31] for example. Since the distinction between sorts (of imaginary elements) will be relevant here, and since some notions and results are simplified when considering $\omega$-categorical simple theories, compared with simple theories in general, we will nevertheless rehearse some notions and results that will be used.

Let $V$ be a vocabulary and $\mathcal{M}$ a $V$-structure. For every $0 < n < \omega$ and $\emptyset$-definable equivalence relation $E$ on $M^n$, $V^{eq}$ (the vocabulary of $\mathcal{M}^{eq}$) contains a unary relation symbol $P_E$ and a relation symbol $F_E$ of arity $n + 1$ (both of which do not belong to $V$), where $P_E$ is interpreted in $\mathcal{M}^{eq}$ as the set of $E$-equivalence classes and $F_E$ is interpreted as the graph of the function which sends every $\bar{a} \in M^n$ to its equivalence class. A sort of $\mathcal{M}^{eq}$ is, by definition, a set of the form $S_E = \{a \in M^{eq} : \mathcal{M}^{eq} \models P_E(a)\}$ for some $E$ as above. If $A \subseteq M^{eq}$ and there are only finitely many $E$ such that $A \cap S_E \neq \emptyset$, then we say that only finitely many sorts are represented in $A$. The identity relation, $'=', is clearly a $\emptyset$-definable equivalence relation on $M$ and every $=\text{-class}$ is a singleton. Therefore $M$ can (and will) be identified with the sort $S_=$, which we call the real sort, so $M \subseteq M^{eq}$. Below follow some facts and definitions. See for example [1] for explanations or proofs of these facts.

**Fact 2.3.** Suppose that $\mathcal{M}$ is $\omega$-categorical and countable, let $A \subseteq M^{eq}$ and suppose that only finitely many sorts are represented in $A$.
(i) For every $n < \omega$ and finite $B \subseteq M^{eq}$, only finitely many types from $S_n^{M^{eq}}(\text{acl}_{M^{eq}}(B))$ are realized by $n$-tuples in $A^n$.
(ii) If $B \subseteq M^{eq}$ is finite and $\bar{a} \in M^{eq}$, then $\text{tp}_{M^{eq}}(\bar{a}/\text{acl}_{M^{eq}}(B))$ is isolated.
(iii) If $B \subseteq M^{eq}$ is finite, $n < \omega$ and $p \in S_n^{M^{eq}}(\text{acl}_{M^{eq}}(B))$ is realized in some elementary extension of $\mathcal{M}^{eq}$ by an $n$-tuple of imaginary elements (i.e. elements satisfying $P_E(x)$ for some, not necessarily the same, $E$), then $p$ is realized in $\mathcal{M}^{eq}$.

**Definition 2.4.** (i) We say that a structure $\mathcal{N}$ is canonically embedded in $\mathcal{M}^{eq}$ if $\mathcal{N}$ is a $\emptyset$-definable subset of $M^{eq}$ and for every $0 < n < \omega$ and every relation $R \subseteq N^n$ which is $\emptyset$-definable in $\mathcal{M}^{eq}$ there is a relation symbol in the vocabulary of $\mathcal{N}$ which is interpreted as $R$ and the vocabulary of $\mathcal{N}$ contains no other relation symbols (and no constant or function symbols).
(ii) In particular, if $R$ is an equivalence relation on $M$ which is $\emptyset$-definable in $\mathcal{M}$, then $\mathcal{M}/R$ denotes the canonically embedded structure with universe $M/R$, where $M/R$ is the set of all equivalence classes of $R$ (which is a $\emptyset$-definable subset of $M^{eq}$).

We immediately get the following:
**Fact 2.5.** If $\mathcal{N}$ is canonically embedded in $\mathcal{M}^{eq}$, then for all $\bar{a}, \bar{b} \in N$ and all $C \subseteq N$, $acl_{\mathcal{N}}(C) = acl_{\mathcal{M}^{eq}}(C) \cap N$ and $tp_{\mathcal{N}}(\bar{a}/C) = tp_{\mathcal{N}}(\bar{b}/C)$ if and only if $tp_{\mathcal{M}^{eq}}(\bar{a}/C) = tp_{\mathcal{M}^{eq}}(\bar{b}/C)$.

Suppose that $T$ is a complete simple theory. For every type $p$ (possibly over a set of parameters) with respect to $T$, there is a notion of SU-rank of $p$, denoted $SU(p)$ (which is either an ordinal or undefined).

See for instance [4, 31] for definitions and basic results about SU-rank. As usual, we abbreviate $SU(tp(\bar{a}/A))$ with $SU(\bar{a}/A)$ and $SU(\bar{a}/\emptyset)$ with $SU(\bar{a})$. (When using this notation there will be no ambiguity about which structure we work in.) If $SU(\bar{a})$ is finite for every $\mathcal{M} \models T$ and every $\bar{a} \in M$, then we say that $T$ (and any $\mathcal{M} \models T$) has finite SU-rank.

**Definition 2.6.** Let $T$ be a complete simple theory.

(i) We say that $T$ has trivial dependence if, whenever $\mathcal{M} \models T$, $A, B, C_1, C_2 \subseteq M^{eq}$ and $A \subseteq_B (C_1 \cup C_2)$, then $A \subseteq_B C_i$ for $i = 1$ or $i = 2$.

(ii) $T$ (as well as every model of it) is 1-based if for every $\mathcal{M} \models T$ and all $A, B \subseteq M^{eq}$, $A$ is independent from $B$ over $acl_{\mathcal{M}^{eq}}(A) \cap acl_{\mathcal{M}^{eq}}(B)$.

For homogeneous structures the notions of 1-basedness, triviality of dependence and finiteness of rank are fairly tightly connected, in particular in the binary case.

**Fact 2.7.** (i) Suppose that $\mathcal{M}$ is homogeneous, simple and 1-based. Then $Th(\mathcal{M})$ has trivial dependence and finite SU-rank (so in particular it is supersimple).

(ii) Suppose that $\mathcal{M}$ is binary, homogeneous and simple. Then $\mathcal{M}$ has finite SU-rank. Also, the following three conditions are equivalent: (a) $\mathcal{M}$ is 1-based, (b) $\mathcal{M}$ has trivial dependence, and (c) every type (over a finite set of parameters) of SU-rank 1 has trivial pregeometry (given by algebraic closure restricted to that type).

**Proof.** (i) Let $\mathcal{M}$ satisfy the premisses of part (i) of the lemma, so it follows that $\mathcal{M}$ is $\omega$-categorical. By Theorem 1.1 in [25], it is not possible to interpret an infinite group in $\mathcal{M}$, which, with the terminology of [25], means that it is not possible to define, with finitely many parameters, an infinite group in $\mathcal{M}^{eq}$. Corollary 3.23 in [9] implies that if $Th(\mathcal{M})$ does not have trivial dependence, then an infinite group is definable, with finitely many parameters, in $\mathcal{M}^{eq}$. It follows that $\mathcal{M}$ must have trivial dependence. And finally, Corollary 4.7 in [14] says that every simple, 1-based and $\omega$-categorical theory is supersimple with finite SU-rank.

(ii) The first claim is the main result of [20]. The second claim follows by combining results from [9, 14, 25] and is explained in some more detail in the introduction to [20]. □

**Definition 2.8.** Let $\mathcal{M}$ be a simple structure. We say that $\mathcal{M}$ has height 1 if there is a $\emptyset$-definable $D \subseteq M^{eq}$ in which only finitely many sorts are represented and $M \subseteq acl_{\mathcal{M}^{eq}}(D)$ and $SU(d) = 1$ for every $d \in D$.

**2.4. Random structures.**

**Definition 2.9.** Let $V$ be a binary vocabulary and let $\mathcal{M}$ be an infinite homogeneous $V$-structure.

(i) A finite $V$-structure $\mathcal{A}$ is called a forbidden structure with respect to $\mathcal{M}$ if $\mathcal{A}$ cannot be embedded into $\mathcal{M}$.

(ii) Suppose that $\mathcal{A}$ is a forbidden structure with respect to $\mathcal{M}$. We call $\mathcal{A}$ a minimal forbidden structure with respect to $\mathcal{M}$ if no proper substructure of $\mathcal{A}$ is a forbidden structure with respect to $\mathcal{M}$.

(iii) We call $\mathcal{M}$ a binary random structure if there does not exist a minimal forbidden structure $\mathcal{A}$ with respect to $\mathcal{M}$ such that $|A| \geq 3$. 

Remark 2.10. (i) It is straightforward to see that the above definition of a binary random structure is equivalent to the definition given in [1, Section 2.3].

(ii) The Rado graph, usually called random graph in model theory, is of course an example of a binary random structure.

(iii) Suppose that $\mathcal{M}$ is a binary random structure. Let $x_1, \ldots, x_n$, where $n \geq 3$, be distinct variables and, for all $1 \leq i < j \leq n$, let $p_{i,j}(x_i, x_j) \in S_2^\mathcal{M}(\emptyset)$. Moreover assume that for all $i < j$ and all $i' < j'$, if $k \in \{i, j\} \cap \{i', j'\}$, then the restriction of $p_{i,j}$ to $x_k$ is identical to the restriction of $p_{i',j'}$ to $x_k$. It now follows straightforwardly from the definition of a binary random structure that $\bigcup_{1 \leq i < j \leq n} p_{i,j}(x_i, x_j)$ is consistent with $Th(\mathcal{M})$ and realized in $\mathcal{M}$. Since $\mathcal{M}$ is homogeneous it also follows that, for any $1 \leq i < j \leq n$, if $\mathcal{M} \models p_{i,j}(a_i, a_j)$ then there are $a_k \in M$ for all $k \in \{1, \ldots, n\} \setminus \{i, j\}$ such that $\mathcal{M} \models \bigwedge_{1 \leq k < l \leq n} p_{k,l}(a_k, a_l)$.

Fact 2.11. Let $\mathcal{M}$ be a binary random structure. Then $Th(\mathcal{M})$ is simple, has $SU$-rank 1 and is 1-based with trivial dependence.

Proof sketch. Let $\mathcal{M}$ be a binary random structure, so it is homogeneous. That $Th(\mathcal{M})$ is simple, has $SU$-rank 1 and trivial dependence is proved in essentially the same way as the (folklore) result that the random graph has these properties. It now follows from Corollary 4.7 in [14] (where the terminology ‘modular’ is used in stead of ’1-based’) that $Th(\mathcal{M})$ is 1-based.

The proofs of the main results, Theorems 1.1 and 1.2, use the notion of reduct and Fact 2.13, below, from [1].

Definition 2.12. Let $\mathcal{M}$ and $\mathcal{N}$ be structures which need not have the same vocabulary. We say that $\mathcal{M}$ is a reduct of $\mathcal{N}$ if they have the same universe ($M = N$) and for every $0 < n < \omega$, if $R \subseteq M^n$ is $\emptyset$-definable in $\mathcal{M}$, then it is $\emptyset$-definable in $\mathcal{N}$.

Fact 2.13. [1] Let $\mathcal{M}$ be countable, binary, homogeneous and simple with trivial dependence. Suppose that $G \subseteq M^{eq}$ is $\emptyset$-definable, only finitely many sorts are represented in $G$, and $SU(a) = 1$ and $acl_{M^{eq}}(a) \cap G = \{a\}$ for every $a \in G$. Let $G$ denote the canonically embedded structure in $M^{eq}$ with universe $G$. Then $G$ is a reduct of a binary random structure.

2.5. Interpretability.

Definition 2.14. Let $\mathcal{M}$ and $\mathcal{N}$ be structures, possibly with different vocabularies.

(i) We say that $\mathcal{N}$ is strongly interpretable in $\mathcal{M}$ if there are

- $0 < n < \omega$,
- a formula $\chi(x_1, \ldots, x_n)$ without parameters in the language of $\mathcal{M}$,
- a bijective function $f : \chi(\mathcal{M}) \rightarrow N$, and
- for every $0 < k < \omega$ and formula $\varphi(x_1, \ldots, x_k)$ without parameters in the language of $\mathcal{N}$, a formula $\psi_\varphi(\bar{y_1}, \ldots, \bar{y_k})$ without parameters in the language of $\mathcal{M}$, such that, for all $\bar{a_1}, \ldots, \bar{a_k} \in \chi(\mathcal{M})$,

$$\mathcal{M} \models \psi_\varphi(\bar{a_1}, \ldots, \bar{a_k}) \iff \mathcal{N} \models \varphi(f(\bar{a_1}), \ldots, f(\bar{a_k})).$$

(ii) We say that $\mathcal{N}$ is definable in $\mathcal{M}$ if $\mathcal{N}$ is strongly interpretable in $\mathcal{M}$ and it is possible to choose $n = 1$ in the definition of ‘strongly interpretable’.

It is immediate that if $\mathcal{N}$ is strongly interpretable in $\mathcal{M}$, then $\mathcal{N}$ is interpretable in $\mathcal{M}$ in the sense of Chapter 5.3 in [17], and $\mathcal{N}$ is interpretable in $\mathcal{M}$ in the sense of [25], and it is definable in $M^{eq}$ in the sense of [9]. The following will be convenient to use.

Lemma 2.15. Suppose that there are positive integers $l, n_1, \ldots, n_l$, formulas $\chi_i(x_1, \ldots, x_{n_i})$ for $i = 1, \ldots, l$, a bijective function $f : \bigcup_{i=1}^l \chi_i(\mathcal{M}) \rightarrow N$ and, for every $0 < k < \omega$,
1 ≤ i ≤ l and formula ϕ(x₁, ..., xₖ) without parameters in the language of N, a
formula ψᵢ,₁(y₁, ..., yₖ) without parameters in the language of M, such that, for all
a₁, ..., ¹k ∈ χᵢ(M),

\[ M \models ψᵢ,₁(a₁, ..., ¹k) \iff N \models ϕ(f(a₁), ..., f(¹k)). \]

Then N is strongly interpretable in M.

Proof sketch. Let n be the maximum of n₁, ..., nₙ. Now the idea is that for every
i = 1, ..., l and ¹a = (a₁, ..., aᵢ) ∈ χᵢ(M), ¹a can be “translated” into an n-tuple ¹a' =
(a₁', ..., aᵢ') where aⱼ' = aⱼ for j = 1, ..., nᵢ and aⱼ' = aᵢ', for j = nᵢ, ..., n. In this
way the set \{ ¹a' : ¹a ∈ χᵢ(M) \} is \emptyset-definable in M, and it follows that the union of these
sets, for i = 1, ..., l, is also \emptyset-definable in M. The rest is straightforward, via obvious
modifications of f and ψᵢ,₁ for each ϕ.

\[ \square \]

3. Binary homogeneous 1-based structures

In this section we prove the main results, Theorems 1.1 and 1.2. Throughout this section
we make the following assumption, which is shared by both theorems:

\[ M \] is countable, binary, homogeneous, simple and 1-based.

Now Fact 2.7 implies that

Th(M) has trivial dependence and is supertomic with finite rank.

Throughout this section and Section 4 we use the following notational convention:

Notation 3.1. The notations acl( ), dcl( ) and tp( ) are abbreviations of aclₘₑₙ( ),
dclₘₑₙ( ) and tpₘₑₙ( ), respectively. However, when speaking of algebraic closure,
definable closure or types in some other structure (M for example), then we will show
this explicitly with a subscript.

The first step is is to use results from [10] to show that every a ∈ M has finitely many
“coordinates” of rank 1 in Mₑₙ which to a large extent determine the properties of a. By
the results in Section 3 of [10], there is a self-coordinatized set C ⊆ Mₑₙ, in the sense of
Definition 3.3 in [10], such that

(3.1) \[ M ⊆ C, C is \emptyset-definable; \]
there are 0 < r < ω and \emptyset-definable sets C₀ ⊆ C₁ ⊆ ... ⊆ Cᵣ ⊆ C such that
C₀ = \emptyset, and for every n < r and every a ∈ Cᵣ₊₁, \text{SU}(a/C_n) = 1;
for all n ≤ r, if a ∈ C_n, b ∈ Mₑₙ and tp(a) = tp(b), then b ∈ C_n;
only finitely many sorts are represented in C; and
M ⊆ C ⊆ acl(Cᵣ).

We assume that

C is chosen so that r is minimal such that (3.1) holds.

As explained in Remark 3.9 of [10], the number r is an invariant of Th(M). The next
lemma shows that the terminology “the height is 1” in the sense of [10] is equivalent with
saying that “the height is 1” in the sense of Definition 2.8.

Lemma 3.2. The following are equivalent:

\[ (1) \quad r = 1. \]
\[ (2) \quad There is a \emptyset-definable D ⊆ Mₑₙ in which only finitely many sorts are represented \]
such that M ⊆ acl(D) and \text{SU}(d) = 1 for every d ∈ D.
Lemma 3.3. If $\mathcal{M}$ is primitive, then $r = 1$, so $M \subseteq \text{acl}(C_1)$.

Proof. Suppose that $\mathcal{M}$ is primitive. Towards a contradiction, suppose that $r > 1$. Consider the following equivalence relation on $M$:

$$x \sim y \iff \text{acl}(x) \cap C_{r-1} = \text{acl}(y) \cap C_{r-1}.$$  

By Fact 2.3, this relation is $\emptyset$-definable in $\mathcal{M}$. By the assumption that $r > 1$ and that $r$ is minimal such that (3.1) holds, there is $a \in M$ such that $a \notin \text{acl}(C_{r-1})$. Hence $a \notin \text{acl}(\text{acl}(a) \cap C_{r-1})$. Then (by Fact 2.3) there is $a' \in M$ such that $a' \neq a$ and

$$\text{tp}(a'/\text{acl}(a) \cap C_{r-1}) = \text{tp}(a/\text{acl}(a) \cap C_{r-1}).$$

It follows that $\text{acl}(a') \cap C_{r-1} = \text{acl}(a) \cap C_{r-1}$, so $a \sim a'$. By the assumption that $\mathcal{M}$ is primitive, we must have $b \sim a$ for all $b \in M$. In other words,

$$\text{acl}(b) \cap C_{r-1} = \text{acl}(a) \cap C_{r-1}.$$  

Let $A = \text{acl}(a) \cap C_{r-1}$, so $A$ is finite; let $\bar{a}$ enumerate $A$. Since, by (3.1) (and properties of dividing), $\text{SU}(b) \geq 1$ for every $b \in A$, there is $b \in C_{r-1}$ such that $\text{rng}(b) \neq A$ and $\text{tp}(b) = \text{tp}(\bar{a})$. Hence there is $a'' \in M$ such that

$$\text{acl}(a'') \cap C_{r-1} = \text{rng}(b) \neq A = \text{acl}(a) \cap C_{r-1},$$

which contradicts (3.2). Hence $r = 1$ and now (3.1) immediately gives that $M \subseteq \text{acl}(C_1)$.

Our aim is to prove Theorems 1.1 and 1.2 where it is assumed that $\mathcal{M}$ is primitive or has weight 1. It follows from the definition of having height 1 (Definition 2.8) and Lemmas 3.2 and 3.3 that in either case we have $r = 1$. Therefore

we assume for the rest of this section that $r = 1$, so $M \subseteq \text{acl}(C_1)$.

By (3.1), for every $c \in C_1$, $\text{SU}(c) = 1$. As dependence is trivial it follows that if $c \in C_1$, $A \subseteq C_1$ and $c \in \text{acl}(A)$, then $c \in \text{acl}(a)$ for some $a \in A$. Now consider the equivalence relation `$\text{acl}(x) \cap C_1 = \text{acl}(y) \cap C_1$’ on $C_1$. By Fact 2.3 this relation is $\emptyset$-definable and there is $t < \omega$ such that every equivalence class has at most $t$ elements. Since $\mathcal{M}^\text{eq}$ has elimination of imaginaries (see [17, 30]) it follows that each equivalence class corresponds to an element in $\mathcal{M}^\text{eq}$ in the following sense: There is a $\emptyset$-definable set $C'_1 \subseteq M^\text{eq}$ in which only finitely many sorts are represented and a $\emptyset$-definable surjective function $f : C_1 \rightarrow C'_1$ (meaning that the graph of $f$ is a $\emptyset$-definable relation) such that if $c, c' \in C_1$ then $f(c) = f(c')$ if and only if $\text{acl}(c) \cap C_1 = \text{acl}(c') \cap C_1$. It follows that for every $c \in C_1$, $f(c) \in \text{dcl}(c)$ and $c \in \text{acl}(f(c))$. This implies that $M \subseteq \text{acl}(C'_1)$ and if $c \in C'_1$, then $\text{SU}(c) = 1$ and $\text{acl}(c) \cap C'_1 = \{c\}$. Since dependence is trivial, it follows that $\text{acl}(A) \cap C'_1 = A$ for every $A \subseteq C'_1$. In order not to switch from the notation ‘$C'_1$’ to the notation ‘$C'_1$’, we may (by the above argument), without loss of generality, assume that

$$\text{acl}(A) \cap C_1 = A.$$  

Definition 3.4. For every $a \in M^\text{eq}$, let $\text{crd}(a) = \text{acl}(a) \cap C_1$. We call ‘$\text{crd}(a)$’ the (set of) coordinates of $a$. (Our definition of $\text{crd}$ corresponds to the notation $\text{crd}_1$ in [10].)

From the definition we obviously have $\text{crd}(a) \subseteq \text{acl}(a)$ for every $a \in M$. 

Lemma 3.5. (i) For every $a \in M$, $a \in \text{acl}(\text{crd}(a))$ and hence $\text{acl}(a) = \text{acl}(\text{crd}(a))$.
(ii) For all $a, a' \in M$, $\text{acl}_M(a) = \text{acl}_M(a')$ if and only if $\text{crd}(a) = \text{crd}(a')$.
(iii) If the equivalence relation $\text{acl}_M(x) = \text{acl}_M(y)$ has only singleton classes, then $a \in \text{dcl}(\text{crd}(a))$ for every $a \in M$.

Proof. Part (i) is a direct consequence of Lemma 5.1 in [10], but can easily be proved directly as follows. Let $a \in M$, so $a \in \text{acl}(C_1)$. Let $B = \text{acl}(a) \cap C_1$. Suppose that $a \notin \text{acl}(B)$. Then $a \not\equiv_B C_1$. As dependence is trivial there is $c \in C_1 \setminus B$ such that $a \not\equiv_B c$ and hence $aB \not\equiv c$ Since $B \subseteq \text{acl}(a)$ we get $a \not\equiv_B c$ which (as $\text{SU}(c) = 1$) implies that $c \in \text{acl}(a)$. Hence $c \in B$ which contradicts the choice of $c$.

Part (ii) follows immediately from part (i) and the definition of $\text{crd}$. Hence it remains to prove (iii).

Suppose that $a, a' \in M$ and $a' \in \text{acl}(\text{crd}(a))$. By the primitivity of $\mathcal{M}$ we have $\text{tp}(a) = \text{tp}(a')$, hence $|\text{crd}(a)| = |\text{crd}(a')|$ and therefore $\text{crd}(a) = \text{crd}(a')$. Hence $a$ and $a'$ belong to the same equivalence class of $\text{acl}_M(x) = \text{acl}_M(y)$ and thus $a = a'$. \qed

Remark 3.6. Let $\approx$ be the ($\emptyset$-definable) equivalence relation `$\text{acl}_M(x) = \text{acl}_M(y)$' and $\mathcal{M}/\approx$ the canonically embedded structure of $\mathcal{M}^{eq}$ with universe $M/\approx$. For every $a \in M$ we have $\text{acl}(a) = \text{acl}([a]_{\approx})$. Therefore $\text{crd}(a) = \text{crd}([a]_{\approx})$ for every $a \in M$ and Lemma 3.5 holds if `$\mathcal{M}$' and `$\mathcal{M}'$ are replaced with `$M/\approx$' and `$\mathcal{M}/\approx$', respectively. Since the equivalence relation `$\text{acl}_M/\approx(x) = \text{acl}_M/\approx(y)$' is trivial it follows that part (iii) simplifies to the statement: for every $a \in M/\approx$, $a \in \text{dcl}(\text{crd}(a))$

Lemma 3.7. If $a, b \in M$ and $\text{tp}(a) = \text{tp}(b)$, then $\text{crd}(a)$ and $\text{crd}(b)$ can be ordered as $\bar{a}$ and $\bar{b}$, respectively, so that $\text{tp}(\bar{a}) = \text{tp}(\bar{b})$.

Proof. Suppose that $a, b \in M$ and $\text{tp}(a) = \text{tp}(b)$. Let $\bar{a}$ be an ordering of $\text{crd}(a)$ and let $f$ be an automorphism of $\mathcal{M}^{eq}$ such that $f(a) = b$. Then $f(\bar{a})$ is an ordering of $\text{crd}(b)$ such that $\text{tp}(\bar{a}) = \text{tp}(f(\bar{a}))$. \qed

By considering a $\emptyset$-definable subset of $C_1$ if necessary, we may, in addition to previous assumptions, assume that

\[(3.4) \quad \text{for every } c \in C_1, \text{ there is } a \in M \text{ such that } c \in \text{crd}(a).\]

Let $C_1$ be the canonically embedded structure in $\mathcal{M}^{eq}$ with universe $C_1$. By Fact 2.13, $C_1$ is a reduct of a binary random structure $\mathcal{R}$, so in particular $R = C_1$, where $R$ is the universe of $\mathcal{R}$. Hence $\text{crd}(a) \subseteq R$ for every $a \in M$.

Proposition 3.8. Let `$\approx$' be the $\emptyset$-definable equivalence relation on $M$ defined by $x \approx y$ if and only if $\text{acl}(x) = \text{acl}(y)$. Then $M/\approx$ is definable in $\mathcal{R}^{eq}$ and we can use a formula $\chi(x)$ and bijection $f : \chi(\mathcal{R}^{eq}) \to M/\approx$ as in Definition 2.14 with the properties that

1. for all $c \in \chi(\mathcal{R}^{eq})$, $\text{acl}_{\mathcal{R}^{eq}}(c) \cap R = \text{crd}(f(c))$ and $\text{acl}_{\mathcal{R}^{eq}}(c) = \text{acl}_{\mathcal{R}^{eq}}(\text{crd}(f(c)))$,
2. for all $c, c' \in \chi(\mathcal{R}^{eq})$, $c = c'$ if and only if $\text{crd}(f(c)) = \text{crd}(f(c'))$,
3. $c \in \text{dcl}_{\mathcal{R}^{eq}}(\text{acl}_{\mathcal{R}^{eq}}(c) \cap R)$ for all $c \in \chi(\mathcal{R}^{eq})$.

Proof. In order to simplify notation and make the argument more clear we prove the proposition under the extra assumption that $\approx$ is trivial, in other words, that it has only singleton classes. The general case is a straightforward modification of this special case, where we use Remark 3.6 instead of Lemma 3.5. The assumption that $\approx$ is trivial implies that $\mathcal{M}/\approx$ is definable in $\mathcal{M}$ via the map taking every $a \in M$ to $[a]_{\approx}$, where $[a]_{\approx}$ is the (singleton) $\approx$-class to which $a$ belongs. Hence it suffices to show that $\mathcal{M}$ is definable in $\mathcal{R}^{eq}$.

Observe that since $C_1$ is a reduct of $\mathcal{R}$ we can (and will) view $(C_1)^{eq}$ as a reduct of $\mathcal{R}^{eq}$. Also, since $C_1$ is canonically embedded in $\mathcal{M}^{eq}$ we can (and will) assume that
$(C_1)^{eq} \subseteq (M^{eq})^{eq}$. Moreover, as $C_1$ is canonically embedded in $M^{eq}$, for all $c, c' \in (C_1)^{eq}$, $tp_{(M^{eq})^{eq}}(c) = tp_{(M^{eq})^{eq}}(c')$ if and only if $tp_{(M^{eq})^{eq}}(\bar{c}) = tp_{(M^{eq})^{eq}}(\bar{c'})$. 

Let $p_1, \ldots, p_s$ enumerate (without repetition) $S_1^M(\emptyset)$. For each $p_i$ choose a realization $a_i \in M$ of $p_i$ and enumerate (without repetition) $\text{crd}(a_i)$ as $b_i$. Then let $q_i = tp(b_i)$. Since $M$ is $\omega$-categorical and since $C_1$ is canonically embedded in $M^{eq}$ and $C_1$ is a reduct of $R$ it follows that (for each $i$) the set $q_i(M^{eq})$ is $\emptyset$-definable in $M^{eq}$, $C_1$ and in $R$.

For each $i$, define an equivalence relation on $q_i(M^{eq})$ as follows: $\bar{x} \sim_i \bar{y}$ if and only if $\text{rng}(\bar{x}) = \text{rng}(\bar{y})$. The relation $\sim_i$ can be extended to all $|b_i|$-tuples of elements from $M^{eq}$, $R$ or $C_1$, by saying that all $|b_i|$-tuples outside of $q_i(M^{eq})$ belong to the same class. Note that $\sim_i$ is a $\emptyset$-definable relation in $R$ as well as in $C_1$ and in $M^{eq}$. Hence, for every $i$, the set of $\sim_i$-classes of tuples in $q_i(M^{eq})$ is a $\emptyset$-definable subset of $R^{eq}$, of $(C_1)^{eq}$ and of $(M^{eq})^{eq}$.

For every $i$ and $\bar{b}$ realizing $q_i$ let $[\bar{b}]_i$ be its $\sim_i$-class. Then let

$$X = \{ c : c = [\bar{b}]_i \text{ for some } i \text{ and } \bar{b} \}$$

so $X$ is a subset of $R^{eq}$, $(C_1)^{eq}$ and of $(M^{eq})^{eq}$. Moreover, $X$ is $\emptyset$-definable in $R^{eq}$ by some formula $\chi(x)$.

Now we define a bijection $g : M \to X$ such that if $f = g^{-1}$ then $f$ has the required properties. For every $a \in M$ define $g(a)$ as follows: let $i$ be such that $M \models p_i(a)$ and (using Lemma 3.7) let $\bar{b}$ enumerate $\text{crd}(a)$ in such a way that $\bar{b}$ realizes $q_i$ and let $g(a) = [\bar{b}]_i$. The surjectivity of $g$ follows from the $\omega$-homogeneity of $M^{eq}$ and the definition of $X$. Observe that if $a \in M$ realizes $p_i$ and $\bar{b}$ enumerates $\text{crd}(a)$ in such a way that it realizes $q_i$ then (by Lemma 3.5) $\text{acl}(\bar{b}) = \text{acl}(a)$ and $[\bar{b}]_i \in \text{dcl}(\text{acl}(a))$. Since each $\sim_i$-class is finite we get $\text{acl}_{(M^{eq})^{eq}}([\bar{b}]_i) = \text{acl}_{(M^{eq})^{eq}}(a)$. As we assume that the equivalence relation $\text{acl}_M(x) = \text{acl}_M(y)$ has only singleton classes (and hence the same holds for $\text{acl}_{(M^{eq})^{eq}}(x) = \text{acl}_{(M^{eq})^{eq}}(y)$) it follows that $g : M \to X$ is bijective and $a \in \text{dcl}_{(M^{eq})^{eq}}(g(a))$ for all $a \in M$. (In the general case, note that the equivalence relation $\text{acl}_{M/\approx}(x) = \text{acl}_{M/\approx}(y)$ is trivial, by the definition of $\approx$.)

Let $0 < n < \omega$ and $a_1, \ldots, a_n, a'_1, \ldots, a'_n \in M$. By the observations already made (following from the fact that $C_1$ is a reduct of $R$ and $C_1$ is canonically embedded in $M^{eq}$) and in particular since $a_i \in \text{dcl}_{(M^{eq})^{eq}}(g(a_i))$ for all $i$ and similarly for $a'_i$ we get:

$$tp_{R^{eq}}(g(a_1), \ldots, g(a_n)) = tp_{R^{eq}}(g(a'_1), \ldots, g(a'_n)) \implies$$

$$tp_{(C_1)^{eq}}(g(a_1), \ldots, g(a_n)) = tp_{(C_1)^{eq}}(g(a'_1), \ldots, g(a'_n)) \implies$$

$$tp_{(M^{eq})^{eq}}(g(a_1), \ldots, g(a_n)) = tp_{(M^{eq})^{eq}}(g(a'_1), \ldots, g(a'_n)) \implies$$

$$tp_{(M^{eq})^{eq}}(a_1, \ldots, a_n) = tp_{(M^{eq})^{eq}}(a'_1, \ldots, a'_n) \implies$$

$$tp_{M}(a_1, \ldots, a_n) = tp_{M}(a'_1, \ldots, a'_n).$$

As $R$ is homogeneous, every type over $\emptyset$ with respect to $R^{eq}$ which is realized by elements from $X$ is isolated. Moreover, for each $0 < n < \omega$, only finitely many types from $S_n^{R^{eq}}(\emptyset)$ are realized by $n$-tuples from $X^n$. It follows that for every $0 < n < \omega$ and $p \in S_n^M(\emptyset)$ there is a formula $\varphi_p(x_1, \ldots, x_n)$ without parameters in the language of $R^{eq}$ such that for all $a_1, \ldots, a_n \in M$,

$$M \models p(a_1, \ldots, a_n) \iff R^{eq} \models \varphi_p(g(a_1), \ldots, g(a_n)).$$

This implies that $M$ is definable in $R^{eq}$ via the map $f = g^{-1}$ as in Definition 2.14.

It remains to verify that $f$ has the other properties stated in the proposition. Let $c \in \chi(R^{eq})$, so $c = [\bar{b}]_i$ for some $i$ and some $\bar{b} \in q_i(M^{eq})$. From the definition of $f$ it follows that $\text{rng}(\bar{b}) = \text{crd}(f(c))$, so $\text{acl}_{R^{eq}}(\bar{b}) = \text{acl}_{R^{eq}}(\text{crd}(f(c)))$. As $c = [\bar{b}]_i$ is a finite equivalence class we get $\text{acl}_{R^{eq}}(c) = \text{acl}_{R^{eq}}(\bar{b}) = \text{acl}_{R^{eq}}(\text{crd}(f(c)))$. In particular, $\text{acl}_{R^{eq}}(c) \cap R = \text{acl}_{R^{eq}}(\bar{b}) \cap R$, and since $\bar{b} \in R$ where $R$ is a binary random structure we
get $\text{acl}_{R^\approx}(\bar{b}) \cap R = \text{rng}(\bar{b}) = \text{crd}(f(c))$. Hence $\text{acl}_{R^\approx}(c) \cap R = \text{crd}(f(c))$. This proves (1).

Since $f$ is bijective and the relation $\text{acl}_M(x) = \text{acl}_M(y)$ has only singleton classes (by assumption) it follows (using Lemma 3.5 (ii)) that for all $c, c' \in \chi(R^\approx)$, $c = c'$ if and only if $\text{crd}(f(c)) = \text{crd}(f(c'))$, so (2) is proved. For (3), suppose that $c, c' \in \chi(R^\approx)$ are distinct and that $c' \in \text{acl}_{R^\approx}(\text{acl}_{R^\approx}(c) \cap R) = \text{acl}_{R^\approx}(\text{acl}(f(c))) = \text{acl}_{R^\approx}(c)$. Then $\text{crd}(f(c')) = \text{acl}_{R^\approx}(c') \cap R \subseteq \text{acl}_{R^\approx}(c) \cap R = \text{crd}(f(c))$, so by (2), $|\text{acl}_{R^\approx}(c') \cap R| < |\text{acl}_{R^\approx}(c) \cap R|$. This implies that $\text{tp}_{R^\approx}(c') \neq \text{tp}_{R^\approx}(c)$ whenever $c, c' \in \chi(R^\approx)$ are distinct and $c' \in \text{acl}_{R^\approx}(\text{acl}_{R^\approx}(c) \cap R)$. It follows that $c \in \text{dcl}_{R^\approx}(\text{acl}_{R^\approx}(c) \cap R)$. □

Observe that Proposition 3.8 proves part (i) of Theorem 1.2. We continue by proving part (ii) of Theorem 1.2. Therefore,

we assume for the rest of the section that the equivalence relation $\text{acl}_M(x) = \text{acl}_M(y)$ is trivial.

Then there is an obvious bijection $h : M/\approx \to M$ such that for all $\bar{a}, \bar{b} \in M/\approx$, $\text{tp}(\bar{a}) = \text{tp}(\bar{b})$ if and only if $\text{tp}(h(\bar{a})) = \text{tp}(h(\bar{b}))$. Therefore Proposition 3.8 allows us to identify $M$ with $\chi(R^\approx)$ via the bijection $h$. We now follow the new assumptions:

for the rest of this section we assume that $M$ is a reduct of the canonically embedded structure of $R^\approx$ with universe $M = \chi(R^\approx)$.

Note that the identification $h(f(c)) = c$ for all $c \in \chi(R^\approx)$ together with (1) of Proposition 3.8 implies that

for all $a \in M$, $\text{crd}(a) = \text{acl}_{R^\approx}(a) \cap R$.

Part (3) of Proposition 3.8 and the new assumptions imply that

(3.5) for every $a \in M$, $a \in \text{dcl}_{R^\approx}(\text{crd}(a))$.

Lemma 3.9. Let $a \in M$ and $\text{crd}(a) = \{b_1, \ldots, b_m\}$, where the elements are enumerated without repetition. Then for every nontrivial permutation $\pi$ of $\{1, \ldots, m\}$, $\text{tp}_R(b_1, \ldots, b_m) \neq \text{tp}_R(b_{\pi(1)}, \ldots, b_{\pi(m)})$.

The proof of Lemma 3.9 is given in Section 4, but now we derive a corollary of it.

Corollary 3.10. For every $a \in M$, $\text{crd}(a) \subseteq \text{dcl}_{R^\approx}(a)$.

Proof. Let $a \in M$ and $\text{crd}(a) = \{b_1, \ldots, b_m\}$. If $b_i \notin \text{dcl}_{M^\approx}(a)$ for some $i$, then $\text{tp}_{R^\approx}(a, b_i) = \text{tp}_{R^\approx}(a, b_j)$ for some $j \neq i$, from which it follows (using that $R^\approx$ is $\omega$-homogeneous) that there is a nontrivial permutation $\pi$ of $\{1, \ldots, m\}$ such that $\text{tp}_{R^\approx}(a, b_1, \ldots, b_m) = \text{tp}_{R^\approx}(a, b_{\pi(1)}, \ldots, b_{\pi(m)})$.

Then $\text{tp}_R(b_1, \ldots, b_m) = \text{tp}_R(b_{\pi(1)}, \ldots, b_{\pi(m)})$ which contradicts Lemma 3.9. □

Now we are ready to prove the remaining parts of the main results (and when stating them we repeat the assumptions made in the beginning of this section).

Theorem 1.2 Suppose that $M$ is a structure which is countable, binary, homogeneous, simple and 1-based with height 1. Let $\approx$ denote the equivalence relation $\text{acl}_M(x) = \text{acl}_M(y)$.

(i) Then there is a binary random structure $R$ such that $M/\approx$ is definable in $R^\approx$.

(ii) If, in addition, the equivalence relation $\approx$ is trivial, then $M$ is strongly interpretable in a binary random structure.

Proof. As mentioned above, part (i) follows from Proposition 3.8. So it remains to prove (ii) and for this we adopt the assumption that the equivalence relation $\approx$ is trivial,
as well as all other assumptions that have been made earlier in this section. The proof is similar to the proof of Proposition 3.8. The essential difference is that the assumption that \( \approx \) is trivial together with Lemma 3.9 allows us to reach a stronger conclusion than in Proposition 3.8.

Let \( p_1, \ldots, p_s \) enumerate \( S^M_L(\emptyset) \). For each \( 1 \leq i \leq s \) choose a realization \( a_i \in M \) of \( p_i \) and then choose an ordering \( b_i \) of \( \text{crd}(a_i) \). For each \( i \), let \( \theta_i \) isolate \( \text{tp}_{\mathcal{R}_o}(a_i, b_i) \) and let \( \varphi_i \) isolate \( \text{tp}_{\mathcal{R}}(b_i) \). Let \( X = \varphi_1(\mathcal{R}) \cup \ldots \cup \varphi_s(\mathcal{R}) \).

By (3.5), for every \( b \in X \) there is a unique \( a \in M \) such that \( \mathcal{R}_o^a \models \theta_i(a, b) \) for some \( i \). For every \( b \in X \) we let \( f(b) = a \) for the unique \( a \in M \) such that \( \mathcal{R}_o^a \models \theta_i(a, b) \) for some \( i \). Since \( \text{crd}(a) \) exists as a subset of \( C_1 = R \) for every \( a \in M \) it follows that \( f : X \rightarrow M \) is surjective. Now we claim that \( f \) is injective. For if \( b, b' \in X \) and \( f(b) = f(b') = a \in M \), then \( \mathcal{R}_o^a \models \theta_i(a, b) \land \theta_j(a, b') \) for some \( i, j \). Then \( \text{tp}_{\mathcal{R}_o}(a, b) = \text{tp}_{\mathcal{R}_o}(a, b') \) and \( \text{tp}_{\mathcal{R}}(a, b) = \text{tp}_{\mathcal{R}_o}(a, b') \) from which it follows that \( \text{tp}_{\mathcal{R}_o}(a_i) = \text{tp}_{\mathcal{R}_o}(a_j) \) and \( \text{rng}(b) = \text{rng}(b') \). From the construction it now follows that \( i = j \) and hence \( \text{tp}_{\mathcal{R}_o}(a, b) = \text{tp}_{\mathcal{R}_o}(a, b') \). By Corollary 3.10, \( \text{rng}(b) \subseteq \text{dcl}_{\mathcal{R}_o}(a) \) and \( \text{rng}(b') \subseteq \text{dcl}_{\mathcal{R}_o}(a) \) so we must have \( b = b' \).

Let \( 0 < n < \omega, 1 \leq j \leq s \) and \( b_1, \ldots, b_n, b'_1, \ldots, b'_n \in \varphi_j(\mathcal{R}) \). From the definition of \( f \), its graph is a \( \emptyset \)-definable relation, which implies (since \( f \) is bijective between two \( \emptyset \)-definable subsets of \( \mathcal{R}_o^a \)) that \( \text{rng}(b_i) \subseteq \text{dcl}_{\mathcal{R}_o}(f(b_i)) \) and \( f(b_i) \in \text{dcl}_{\mathcal{R}_o}(b_i) \) for each \( i \), and similarly for each \( b'_i \). This implies that

\[
\begin{align*}
\text{tp}_{\mathcal{R}}(b_1, \ldots, b_n) &= \text{tp}_{\mathcal{R}}(b'_1, \ldots, b'_n) \iff \\
\text{tp}_{\mathcal{R}_o}(b_1, \ldots, b_n) &= \text{tp}_{\mathcal{R}_o}(b'_1, \ldots, b'_n) \iff \\
\text{tp}_{\mathcal{R}_o}(f(b_1), \ldots, f(b_n)) &= \text{tp}_{\mathcal{R}_o}(f(b'_1), \ldots, f(b'_n)) \implies \\
\text{tp}_{\mathcal{M}}(f(b_1), \ldots, f(b_n)) &= \text{tp}_{\mathcal{M}}(f(b'_1), \ldots, f(b'_n)).
\end{align*}
\]

Since \( \mathcal{R} \) and \( \mathcal{M} \) are homogeneous and hence \( \omega \)-categorical, there is for every \( 0 < n < \omega \) and formula \( \xi(x_1, \ldots, x_n) \) in the language of \( \mathcal{M} \) a formula \( \xi'(\overline{x}_1, \ldots, \overline{x}_n) \) in the language of \( \mathcal{R} \) such that for all \( b_1, \ldots, b_n \in \varphi_i(\mathcal{R}) \), \( \mathcal{M} \models \xi'(f(b_1), \ldots, f(b_n)) \) if and only if \( \mathcal{R} \models \xi'(b_1, \ldots, b_n) \). By Lemma 2.15, \( \mathcal{M} \) is strongly interpretable in \( \mathcal{R} \).

**Theorem 1.1** Suppose that \( \mathcal{M} \) is a structure which is countable, binary, homogeneous, primitive, simple and 1-based. Then \( \mathcal{M} \) is strongly interpretable in a binary random structure.

**Proof.** Suppose that \( \mathcal{M} \) satisfies the assumptions of the Theorem 1.1. The primitivity of \( \mathcal{M} \) implies that the equivalence relation \( \text{accl}(x) = \text{accl}(y) \) is trivial, because it is \( \emptyset \)-definable in \( \mathcal{M} \). Therefore Theorem 1.1 is a direct consequence of Lemma 3.3 and Theorem 1.2.

**Examples 3.11.** One can construct structures that satisfy the assumptions of Theorem 1.2 roughly as follows. Take a binary random structure \( \mathcal{R} \). Choose some rigid nonisomorphic substructures \( \mathcal{L}_1, \ldots, \mathcal{L}_k \) of \( \mathcal{R} \) (where rigid means that there is no non-trivial automorphism) together with a fixed enumeration of \( L_i \) for each \( i \). Let \( M \) be the set of substructures of \( \mathcal{R} \) which are isomorphic to some \( \mathcal{L}_i \). If \( \mathcal{L} \cong \mathcal{L}_i \) then we think of \( \mathcal{L} \) as being enumerated so that this enumeration and the enumeration of \( L_i \) induces an isomorphism from \( \mathcal{L} \) to \( L_i \). For any \( A, A', B, B' \in M \), let \( (A, A') \) and \( (B, B') \) have the same type in \( \mathcal{M} \) if and only if \( \bar{a} \bar{a}' \) and \( \bar{b} \bar{b}' \) have the same type in \( \mathcal{R} \) where \( \bar{a}, \bar{a}', \bar{b}, \bar{b}' \) are the enumerations of the elements in the respective structure. By Theorem 1.1 and Lemma 3.9 it follows that if \( N \) is countable, binary, homogeneous, primitive, simple and 1-based, then \( N \) is a proper reduct of such a structure \( \mathcal{M} \) (with \( k = 1 \)).
4. Proof of Lemma 3.9

In this section we prove Lemma 3.9, so all assumptions in Section 3 up to the Lemma 3.9 apply in this section, including the conventions of Notation 3.1. In particular we recall that \( \mathcal{R} \) is a binary random structure and \( C_1 \) is the canonically embedded structure of \( \mathcal{M}^{eq} \) with universe \( C_1 \).

The intuition behind the proof of Lemma 3.9 comes from the argument that the line graph over a complete graph with infinite countable vertex set is not homogeneous. Somewhat more precisely: Suppose that \( K \) is a complete graph with infinite countable vertex set \( K \). The line graph over \( K \) has as its vertex set the set of all 2-subsets of \( K \) and two 2-subsets are adjacent (in the line graph) if and only if they intersect in exactly one point. Then one can choose distinct \( a, b, c \in K \) and distinct \( d, e, e', e'' \in K \) and it is easy to see that the 3-tuples \((\{a, b\}, \{b, c\}, \{c, a\})\) and \((\{d, e\}, \{d, e'\}, \{d, e''\})\) satisfy the same quantifier free formulas in the line graph, but there is a formula which is satisfied by one of the tuples but not the other.

**Lemma 3.9** Let \( a \in M \) and \( \text{crd}(a) = \{b_1, \ldots, b_m\} \), where the elements are enumerated without repetition. Then for every nontrivial permutation \( \pi \) of \( \{1, \ldots, m\} \), \( \text{tp}_R(b_1, \ldots, b_m) \neq \text{tp}_R(b_{\pi(1)}, \ldots, b_{\pi(m)}) \).

**Proof.** As usual we use the facts from Section 2 without further reference. The lemma is trivial if \( m = 1 \), so we assume that \( m \geq 2 \). Let \( a \in M \) and let \( \text{crd}(a) = \{b_1, \ldots, b_m\} \).

Towards a contradiction, suppose that there is a nontrivial permutation \( \pi \) of \( \{1, \ldots, m\} \) such that

\[
\text{(4.1)} \quad \text{tp}_R(b_1, \ldots, b_m) = \text{tp}_R(b_{\pi(1)}, \ldots, b_{\pi(m)}).
\]

To simplify notation and without loss of generality,

\[
\text{(4.2)} \quad \text{we assume that } \pi(1) = 2.
\]

From (4.1) and (4.2) we get

\[
\text{tp}_R(b_1) = \text{tp}_R(b_2).
\]

As \( \mathcal{R} \) is a binary random structure we can argue as in Remark 2.10 (with \( n = 3 \), \( p_{1,2}(x_1, x_2) = \text{tp}_R(b_1, b_2) \), \( p_{1,3}(x_1, x_3) = \text{tp}_R(b_1, b_2) \) and \( p_{2,3}(x_2, x_3) = \text{tp}_R(b_1, b_2) \)) and find \( b'_2 \in R \) such that

\[
\text{tp}_R(b_1, b'_2) = \text{tp}_R(b_1, b_2) = \text{tp}_R(b_2, b'_2).
\]

If \( m > 2 \), then, by using that \( \mathcal{R} \) is a random structure again, we find distinct elements \( b'_3, \ldots, b'_m, b''_3, \ldots, b''_m \in R \) such that if we let

\[
\text{(4.3)} \quad b'_1 = b_1, \quad b''_1 = b_2, \quad b'_2 = b'_2,
\]

then

\[
\text{(4.4)} \quad \text{tp}_R(b_1, b_2, \ldots, b_m) = \text{tp}_R(b'_1, b'_2, \ldots, b'_m) = \text{tp}_R(b''_1, b''_2, \ldots, b''_m).
\]

From (4.1) and (4.4) we get

\[
\text{(4.5)} \quad \text{tp}_R(b_1, b_2, \ldots, b_m) = \text{tp}_R(b_{\pi(1)}, b_{\pi(2)}, \ldots, b_{\pi(m)}),
\]

\[
\text{tp}_R(b'_1, b'_2, \ldots, b'_m) = \text{tp}_R(b'_{\pi(1)}, b'_{\pi(2)}, \ldots, b'_{\pi(m)}) \quad \text{and}
\]

\[
\text{tp}_R(b''_1, b''_2, \ldots, b''_m) = \text{tp}_R(b''_{\pi(1)}, b''_{\pi(2)}, \ldots, b''_{\pi(m)}).
\]
Since $\text{tp}_R(b_1) = \text{tp}_R(b_2) = \text{tp}_R(b'_2)$ and $R$ is a binary random structure it follows from (4.5) that there are $c_2, \ldots, c_m \in R \setminus \{b_1, \ldots, b_m, b'_1, \ldots, b'_m\}$ such that if $c_1 = b_1(= b'_1)$, then

\begin{equation}
\text{C}_1 \text{ is a reduct of } R \text{ we can replace } \text{tp}_R \text{ with } \text{tp}_{C_1} \text{ everywhere in (4.4), (4.5) and (4.6). Moreover, as } C_1 \text{ is a canonically embedded structure of } M^\text{eq}, \text{ we can replace } \text{tp}_{C_1} \text{ with 'tp' (which abbreviates 'tp}_{M^\text{eq}}), so altogether we get}
\end{equation}

(4.7) $\text{tp}(b_1, b_2, \ldots, b_m) = \text{tp}(b'_1, b'_2, \ldots, b'_m) = \text{tp}(b''_1, b''_2, \ldots, b''_m)$,

$\text{and hence } \text{crd}(a^*) = \{c_1, \ldots, c_m\}. \text{ For the same reason there is } a' \in M \text{ such that}

\begin{equation}
\text{tp}(a', b_1, \ldots, b_m) = \text{tp}(a, b_1, \ldots, b_m)
\end{equation}

and hence $\text{crd}(a') = \{b'_1, \ldots, b'_m\}$. By the $\omega$-homogeneity of $M^\text{eq}$ again and (4.7), there are $a_0, a''_0, a''_0 \in M$ such that

(4.8) $\text{tp}(a, b_1, \ldots, b_m, a^*, c_1, \ldots, c_m) = \text{tp}(a_0, b_0, c_1, \ldots, c_m, a', b'_1, \ldots, b'_m)$ and

$\text{and } \text{crd}(a_0) = \{b_1, \ldots, b_m\}, \text{ crd}(a'_0) = \{b'_1, \ldots, b'_m\} \text{ and crd}(a'') = \text{crd}(a''_0) = \{b''_1, \ldots, b''_m\}. \text{ As the equivalence relation } \text{acl}(M(x)) = \text{acl}(M(y)) \text{ is assumed to be trivial it follows from Lemma 3.5 that } a_0 = a, a'_0 = a' \text{ and } a''_0 = a''. \text{ Therefore (4.8) implies that}

\begin{equation}
\text{tp}(a, a'') = \text{tp}(a, a^*) \text{ and } \text{tp}(a', a'') = \text{tp}(a', a^*), \text{ and hence}
\end{equation}

\begin{equation}
\text{tp}_M(a, a'') = \text{tp}_M(a, a^*) \text{ and } \text{tp}_M(a', a'') = \text{tp}_M(a', a^*).
\end{equation}

As $M$ is a homogeneous and binary we get

\begin{equation}
\text{tp}_M(a, a', a'') = \text{tp}_M(a, a', a^*)
\end{equation}

and hence $\text{tp}(a, a', a'') = \text{tp}(a, a', a^*)$. Since (by definition) $\text{crd}(a) = \text{acl}(a) \cap C_1$ and similarly for $a', a''$ and $a^*$, there are permutations $\sigma_1, \sigma_2, \sigma_3$ of $\{1, \ldots, m\}$ such that

\begin{equation}
\text{tp}(b_1, \ldots, b_m, b'_1, \ldots, b''_1, \ldots, b''_m)
\end{equation}

$= \text{tp}(b_{\sigma_1(1)}, \ldots, b_{\sigma_1(m)}, b'_{\sigma_2(1)}, \ldots, b'_{\sigma_2(m)}, c_{\sigma_3(1)}, \ldots, c_{\sigma_3(m)})$.

We have

\begin{equation}
\{b_1, \ldots, b_m\} \cap \{b'_1, \ldots, b'_m\} \cap \{c_1, \ldots, c_m\} \neq \emptyset
\end{equation}

because $b_1 = b'_1 = c_1$ belongs to this intersection, while

\begin{equation}
\{b_1, \ldots, b_m\} \cap \{b'_1, \ldots, b'_m\} \cap \{b''_1, \ldots, b''_m\} = \emptyset
\end{equation}

by the choice of these elements. This contradicts (4.9). □
